

MA4823 Microprocessor

Systems Notes

Hankertrix

Contents

1 Abbreviations	17
1.1 MCU	17
1.2 ARM	17
1.3 RISC	17
1.4 ISA	17
1.5 SVC	17
1.6 FIQ	17
1.7 DMA	17
1.8 SPSR	17
1.9 CPSR	17
1.10 SP	17
1.11 LR	17
1.12 MMU	17
1.13 MPU	17
1.14 AMBA	17
1.15 SoC	17
1.16 APB	17
1.17 AHB	17
1.18 JTAG	18
1.19 RAM	18
1.20 CPU	18
1.21 FET	18
1.22 SRAM	18
1.23 DRAM	18
1.24 SLC	18
1.25 ALU	18
1.26 APSR	18
1.27 EPSR	18
1.28 IPSR	18
1.29 I/O	18
1.30 NVIC	18
1.31 SysTick	18
1.32 Opcode	18
1.33 MSB	18
1.34 LSB	18
1.35 VFP	19
1.36 FPU	19
1.37 MPU	19

1.38	GiB	19
1.39	IDE	19
1.40	I/O or IO	19
1.41	GPIO	19
1.42	ADC	19
1.43	PWM	19
1.44	UART	19
1.45	DTE	19
1.46	DCE	19
1.47	TX or Tx	19
1.48	RX or Rx	19
1.49	GND	19
1.50	BRD	19
1.51	TTL	19
1.52	RTOS	20
1.53	IRQ	20
1.54	ISR	20
2	Definitions	21
2.1	Microprocessor system	21
2.2	Word	21
2.3	Using I/O modules	21
2.4	Bits and bytes	21
2.5	Fast interrupt request (FIQ)	21
2.6	Direct memory access (DMA)	21
2.7	Truth table	21
2.8	Rising edge	22
2.9	Falling edge	22
2.10	Bus	23
2.10.1	Address bus	23
2.10.2	Data bus	23
2.11	Endianness of memory	23
2.12	Base address	23
2.13	Address offset	23
2.14	Address indexing	23
2.15	Configuration register	23
2.16	Maskable data register	24
2.16.1	Example	24
2.16.2	Why have maskable data registers?	24
3	Basics of brains	25
3.1	Characteristics of the human brain	25
3.2	Blueprint of a machine brain	25
3.3	Characteristics of a machine brain	25
3.4	Van Neumann architecture	26
3.5	Harvard architecture	26
4	ARM: Advanced RISC Machines	27
4.1	ARM Family	27
4.2	ARM Cortex uses the RISC architecture	27
4.2.1	Architecture of the ARM7TDMI Processor	28
4.3	Modes in ARM Cortex	28

4.4	Registers in ARM Cortex	29
4.4.1	Register table	30
4.4.2	Current program status register (CPSR, R16)	31
4.4.3	Cortex M4's status register	32
4.5	ARM Cortex as a microcontroller	32
4.6	ARM features	32
4.7	Memory inside TM4C123G	33
4.8	ARM Cortex M's memory space	35
4.8.1	On-chip memory subspace	36
4.8.2	Off-chip memory subspace	36
4.8.3	Private memory subspace	37
4.9	Cortex M4 pin diagram	37
4.10	Cortex M4 table of pin usage	38
4.11	Cortex M4's floating point unit's registers	39
5	Typical types of application software	40
6	Binary logic devices	40
6.1	Binary number systems	40
6.2	Binary logic operations	41
6.3	NOT logic gate	41
6.3.1	Truth table	41
6.3.2	Circuit diagrams	42
6.4	AND logic gate	43
6.4.1	Truth table	43
6.4.2	Circuit diagrams	44
6.5	OR logic gate	45
6.5.1	Truth table	45
6.5.2	Circuit diagrams	46
6.6	XOR logic gate	47
6.6.1	Truth table	47
6.6.2	Circuit diagrams	47
6.7	XNOR logic gate	48
6.7.1	Truth table	48
6.7.2	Circuit diagrams	48
6.8	D flip-flop	49
6.8.1	Truth table	49
6.9	8-bit shift register	50
6.10	Single bit Static RAM (SRAM)	50
6.11	Single bit Dynamic RAM (DRAM)	51
6.12	1-bit flash cell	51
6.12.1	Line of flash cells	52
6.12.2	Writing	52
6.12.3	NOR erasing	52
6.12.4	NOR writing	53
6.12.5	Reading	53
6.12.6	NOR reading	54
7	Number representation	55
7.1	History of number systems	55
7.2	Binary number system	55
7.2.1	Format of binary numbers	55

7.2.2	Integer example	55
7.2.3	Fractional example	55
7.2.4	Binary addition	56
7.2.5	Binary subtraction	57
7.3	Decimal number system	58
7.3.1	Integer example	58
7.3.2	Fractional example	58
7.3.3	Decimal addition	59
7.3.4	Decimal subtraction	60
7.3.5	Hexadecimal number system	61
7.3.6	Integer example	61
7.3.7	Fractional example	61
7.3.8	Hexadecimal addition	62
7.3.9	Hexadecimal subtraction	63
7.3.10	Hexadecimal ASCII table	64
7.4	Conversion look-up table	64
7.4.1	Conversion from binary to hexadecimal	65
7.4.2	Conversion from hexadecimal to binary	65
7.4.3	Conversion from decimal to binary, integer part	66
7.4.4	Conversion from decimal to binary, fractional part	66
7.4.5	Example of converting a decimal number with decimals to binary	67
7.4.6	Conversion from decimal to hexadecimal, integer part	67
7.4.7	Conversion from decimal to hexadecimal, fractional part	68
7.5	Representation of integers	68
7.5.1	Binary-coded decimal of integers	68
7.5.2	Signed magnitude format of integers	68
7.5.3	Two's complement format of integers	69
7.5.4	Reasons to use two's complement format	69
7.6	Representation of floating point numbers	70
7.6.1	Binary-coded decimal of floating-point numbers	70
7.6.2	Exponent-mantissa format of floating point numbers	70
7.6.3	Conversion of decimals to exponent-mantissa format	71
7.6.4	Zero and infinity in exponent-mantissa format	72
8	Nature of programming	72
8.1	Programming versus writing	72
8.2	How to organise your solution?	73
8.2.1	Example of $(x = (a + b) - c)$	73
8.3	Procedure of planning computations	74
8.3.1	Example of transforming a solution into an algorithm	74
8.3.2	Example of flowchart corresponding to algorithm	74
9	Allocation of memory	75
9.1	Why allocate memory?	75
9.2	Memory allocation scenarios	75
9.3	Memory allocation example	76
10	ARM programming tools	76
10.1	Overview	76
10.2	Assembler directives for memory destination (GCC and ArmClang)	77
10.2.1	Example 1	78
10.2.2	Example 2	78

10.2.3	Example 3	79
10.2.4	Example 4	79
10.3	Assembler directives for controlling conditional computations (GCC and ArmClang)	79
10.3.1	Example	80
10.4	Directive for creating reusable block of codes (GCC and ArmClang)	81
10.4.1	Example	81
11	Memory-mapped I/O devices	82
11.1	Data flow	82
11.2	Basic unit of input/output data	82
11.3	Memory allocation	82
11.4	Example of internal data input from port F	83
11.5	TM4C123G GPIO module	85
11.6	TM4C123G ADC module	86
11.7	TM4C123G PWM module	86
11.8	Data organisation nomenclature	87
11.9	Address indexing methods	88
11.9.1	Pre-indexing without write-back	89
11.9.2	Pre-indexing with write-back	89
11.9.3	Post-indexing	89
11.9.4	Example 1: Pre-indexed address without write-back	89
11.9.5	Example 2: Pre-indexed address with write-back	89
11.10	ARM Cortex M4 GPIO ports	90
11.10.1	Read and write example	90
11.10.2	Example with port F	91
11.11	Encoding of instructions in ARM	92
11.11.1	LDR and STR instructions for data I/O	92
11.11.1.1	For sizes other than a word	93
12	Digital input and output (GPIO)	94
12.1	Digital signals	94
12.1.1	Logic levels	94
12.1.2	Transistor-transistor logic (TTL) levels	94
12.1.3	Acceptable input digital signals (TTL levels)	94
12.1.4	Representation and events of digital signals	95
12.1.5	Signal lines of digital signals	95
12.1.6	Tri-state logic	95
12.1.7	Schmitt filters or triggers	95
12.1.8	Principle of Schmitt filters	95
12.1.9	Communication of digital signals	96
12.2	Synchronous digital input and output	96
12.2.1	Working principle of synchronous serial input and output	96
12.2.2	SPI and I2C example	97
12.2.3	Example of an I2C bus	97
12.2.4	Working principle of synchronous parallel input and output	98
12.2.5	Receiver initiated parallel input	99
12.2.6	Transmitter initiated parallel input	100
12.3	Asynchronous digital input and output	101
12.3.1	Working principle of asynchronous digital input and output (data line)	101
12.3.2	Working principle of asynchronous digital input and output (data line)	102
12.3.2.1	Example: Keypad	103

12.3.2.2	Example: LED dot matrix	103
13	Analogue input and outputs	104
13.1	Types of analogue inputs	104
13.2	Types of analogue outputs	104
13.3	Working principle of a digital to analogue converter (DAC)	104
13.3.1	Exercise	105
13.4	Specification of DACs	105
13.4.1	Exercise	105
13.5	Working principle of an analogue to digital converter (ADC)	106
13.5.1	Example: Speech signals	107
13.6	Specification of ADCs	108
13.6.1	Exercise	108
14	Universal asynchronous receiver/transmitter (UART)	109
14.1	Basic elements of a parallel/serial interface	109
14.2	UART connection to external device	110
14.3	Data communication (serial)	110
14.4	Asynchronous serial format (data framing)	110
14.4.1	Standard format	111
14.5	ASCII format	112
14.6	Baud rate (data transmission speed)	113
14.6.1	Example	113
14.7	UART data transmission	114
14.8	Syncing receiver section with serial data	115
14.8.1	Syncing procedure	116
15	Synchronous serial interface (SSI)	117
15.1	UART vs SSI	117
16	Stepper motors	118
16.1	Working principle	118
16.2	Advantages	119
16.3	Disadvantages	119
16.4	Applications	119
16.5	Output control	119
16.5.1	Example	120
17	Brushed DC motors	121
17.1	Working principle	121
17.2	L289N H-bridge motor driver	121
17.2.1	Output control	122
17.2.1.1	PWM logic control	122
17.2.1.2	PWM power control	122
18	Brushless DC motors	123
18.1	Hall effect sensor	123
18.2	Working principle	124
18.3	Sequence	124
18.4	Advantages	126
18.5	Disadvantages	126
19	TM4C123GH6PM General Purpose Input/Output (GPIO)	127
19.1	Key features	127
19.2	Process of operating GPIO	127
19.3	Pin diagram	128

19.4	Analogue and digital I/O pads	129
19.5	GPIO pins and alternate functions	130
19.6	GPIO register map	132
19.7	Registers	133
19.7.1	General-Purpose Input/Output Run Mode Clock Gating Control (RCGCGPIO) .	133
19.7.2	GPIO Digital Enable (GPIODEN)	135
19.7.3	GPIO Direction (GPIODIR)	136
19.7.4	GPIO Interrupt Sense (GPIOIS)	137
19.7.5	GPIO Interrupt Event (GPIOEV)	138
19.7.6	GPIO Interrupt Both Edges (GPIOIBE)	139
19.7.7	GPIO Interrupt Mask (GPIOIM)	140
19.7.8	GPIO 2-mA Drive Select (GPIODR2R)	141
19.7.9	GPIO 4-mA Drive Select (GPIODR4R)	142
19.7.10	GPIO 8-mA Drive Select (GPIODR8R)	143
19.7.11	GPIO Open Drain Select (GPIOODR)	144
19.7.12	GPIO Pull-Up Select (GPIOPUR)	145
19.7.13	GPIO Pull-Down Select (GPIOPDR)	146
19.7.14	GPIO Pins with special considerations	147
19.7.15	GPIO Alternate Function Select (GPIOAFSEL)	148
19.7.16	GPIO Lock (GPIOLOCK)	149
19.7.17	GPIO Commit (GPIOCR)	150
19.7.18	GPIO Analog Mode Select (GPIOAMSEL)	152
19.7.19	GPIO Data (GPIODATA)	153
19.7.19.1	GPIO write example	154
19.7.19.2	GPIO read example	154
19.7.20	GPIO Raw Interrupt Status (GPIOISR)	155
19.7.21	GPIO Masked Interrupt Status (GPIOMIS)	156
19.7.22	GPIO Interrupt Clear (GPIOICR)	157
19.7.23	GPIO Port Control (GPIOPCTL)	158
19.7.24	GPIO ADC Control (GPIOADCCTL)	159
19.8	Initialisation	160
19.8.1	Example	160
19.9	Quick reference	161
20	TM4C123GH6PM Cortex M4 analogue to digital converter (ADC)	162
20.1	Functions	162
20.2	Main features	162
20.3	Implementation of 2 ADC blocks	162
20.4	ADC module block diagram	163
20.5	ADC signal pin names	164
20.6	ADC register map	165
20.7	GPIOPCTL for ADC	166
20.8	Functional description	167
20.9	Registers	168
20.9.1	ADC Peripheral Properties (ADCPP)	168
20.9.2	ADC Peripheral Configuration (ADCPC)	170
20.9.3	Analogue-to-Digital Converter Run Mode Clock Gating Control (RCGCADC) .	171
20.9.4	ADC Sample Sequencer Priority (ADCSSPRI)	172
20.9.5	ADC Control (ADCCTL)	174
20.9.6	ADC Sample Sequence Input Multiplexer Select 0 (ADCSSMUX0)	175

20.9.7	ADC Sample Sequence Input Multiplexer Select n (ADCSSMUXn)	177
20.9.8	ADC Event Multiplexer Select (ADCEMUX)	178
20.9.8.1	Valid configurations for the trigger select fields	179
20.9.9	ADC Trigger Source Select (ADCTSSEL)	180
20.9.10	ADC Clock Configuration (ADCCC)	182
20.9.11	ADC Sample Sequence Control 0 (ADCSSCTL0)	183
20.9.12	ADC Sample Sequence Control n (ADCSSCTLn)	192
20.9.13	ADC Sample Sequence Control 3 (ADCSSCTL3)	198
20.9.14	ADC Active Sample Sequencer (ADCACTSS)	200
20.9.15	ADC Sample Phase Control (ADCSPC)	202
20.9.16	ADC Digital Comparator Range n (ADCDCCMPn)	203
20.9.17	ADC Digital Comparator Reset Initial Conditions (ADCDCRIC)	204
20.9.18	ADC Sample Sequence 0 Digital Comparator Select (ADCSSDC0)	210
20.9.19	ADC Sample Sequence 0 Operation (ADCSSOP0)	212
20.9.20	ADC Processor Sample Sequence Initiate (ADCPSSI)	214
20.9.21	ADC Sample Averaging Control (ADCSAC)	216
20.9.22	ADC Interrupt Mask (ADCIM)	217
20.9.23	ADC Sample Sequence Result FIFO n (ADCSSFIFO _n)	219
20.9.24	ADC Sample Sequence FIFO n Status (ADCSSFSTAT _n)	220
20.9.24.1	Illustration of the head and tail address	221
20.9.25	ADC Raw Interrupt Status (ADCRIS)	222
20.9.26	ADC Digital Comparator Interrupt Status and Clear (ADCDCISC)	224
20.9.27	ADC Interrupt Status and Clear (ADCISC)	226
20.9.28	ADC Overflow Status (ADCOSTAT)	229
20.10	Reference voltages of Cortex M4 ADC	231
20.11	Output from Cortex M4 ADC	231
20.11.1	Exercise	232
20.12	Initialisation	232
20.12.1	Example	233
20.13	Quick reference	235
20.14	Differential sampling	236
20.14.1	Differential sampling pairs	236
20.15	Output of interrupts	236
20.15.1	Low band operation	236
20.15.2	Mid band operation	237
20.15.3	High band operation	237
20.15.4	Hardware output averaging	238
21	TM4C123GH6PM UART	239
21.1	UARTs in Cortex M4	240
21.2	UART module block diagram	241
21.3	J connectors	242
21.3.1	J1 connector	242
21.3.2	J2 connector	243
21.3.3	J3 connector	243
21.3.4	J4 connector	244
21.4	UART description and configuration	245
21.5	UART register map	245
21.6	Essential registers	246
21.7	Registers	247

21.7.1	Universal Asynchronous Receiver/Transmitter Run Mode Clock Gating Control (RCGCUART)	247
21.7.2	UART Integer Baud-Rate Divisor (UARTIBRD)	249
21.7.3	UART Fractional Baud-Rate Divisor (UARTFBRD)	250
21.7.4	UART Line Control (UARTLCRH)	251
21.7.5	UART Clock Configuration (UARTCC)	253
21.7.6	UART DMA Control (UARTDMACTL)	254
21.7.7	UART Control (UARTCTL)	255
21.7.8	UART Data (UARTDR)	260
21.7.9	UART Flag (UARTFR)	262
21.7.10	UART Raw Interrupt Status (UARTRIS)	264
21.7.11	UART Interrupt Mask (UARTIM)	268
21.7.12	UART Masked Interrupt Status (UARTMIS)	271
21.7.13	UART Interrupt Clear (UARTICR)	274
21.7.14	UART Interrupt FIFO Level Select (UARTIFLS)	276
21.8	Initialisation and configuration	278
21.9	UART baud rate settings	278
21.10	Baud rate setting	278
21.10.1	Example	278
21.10.1.1	How to convert fractions in decimal to binary?	279
21.10.1.2	Continuing the example	279
21.10.2	Procedure	279
21.11	UART transmission procedure	280
21.12	UART transmission sequence	280
21.13	UART receiving sequence	281
22	TM4C123GH6PM SSI	281
22.1	SSI pin names	282
22.2	SSI module	283
22.3	J connectors	284
22.3.1	J1 connector	284
22.3.2	J2 connector	285
22.3.3	J3 connector	285
22.3.4	J4 connector	286
22.4	SSI register map	286
22.5	SSI register names	287
22.6	Registers	288
22.6.1	SSI Control 0 (SSICR0)	288
22.6.2	SSI Control 1 (SSICR1)	290
22.6.3	SSI Clock Configuration (SSICC)	292
22.6.4	SSI Clock Prescale (SSICPSR)	293
22.6.5	SSI Status (SSISR)	294
22.6.6	Synchronous Serial Interface Run Mode Clock Gating Control (RCGCSSI)	296
22.6.7	SSI Data (SSIDR)	297
22.7	Connection to I/O device	298
22.8	SSI clock frequency configuration	300
22.9	SSI mode control bits	301
22.10	Initialisation	301
22.11	Configuration	302
22.11.1	Example	302

23	TM4C123GH6PM PWM	303
23.1	Block diagrams	303
23.1.1	PWM module	303
23.1.2	PWM generator block	304
23.2	PWM pins	305
23.3	PWM register map	307
23.4	Registers	310
23.4.1	Run-Mode Clock Configuration (RCC)	310
23.4.1.1	Possible system clock frequencies using SYSDIV field	316
23.4.2	Run Mode Clock Gating Control Register 0 (RCGC0)	317
23.4.3	Run Mode Clock Gating Control Register 2 (RCGC2)	320
23.4.4	PWMn Control (PWMMnCTL)	322
23.4.5	PWMn Generator A Control (PWMMnGENA)	328
23.4.6	PWMn Generator B Control (PWMMnGENB)	330
23.4.7	PWMn Load (PWMMnLOAD)	332
23.4.8	PWMn Compare A (PWMMnCMPA)	333
23.4.9	PWMn Compare B (PWMMnCMPB)	334
23.4.10	PWM Output Enable (PWMENABLE)	335
23.4.11	PWMn Dead-Band Rising-Edge Delay (PWMMnDBRISE)	337
23.4.12	PWMn Dead-Band Falling-Edge-Delay (PWMMnDBFALL)	338
23.4.13	PWMn Fault Source 0 (PWMMnFLTSRC0)	339
23.4.14	PWMn Fault Source 1 (PWMMnFLTSRC1)	341
23.4.15	PWMn Dead-Band Control (PWMMnDBCTL)	345
23.4.16	PWM Time Base Sync (PWMSYNC)	346
23.4.17	PWM Master Control (PWMMCTL)	347
23.4.18	PWMn Minimum Fault Period (PWMMnMINFLTPER)	349
23.4.19	PWMn Fault Pin Logic Sense (PWMMnFLTSEN)	350
23.4.20	PWM Enable Update (PWMMENUPD)	351
23.4.21	PWM Output Inversion (PWMMINVERT)	356
23.4.22	PWM Output Fault (PWMMFAULT)	358
23.4.23	PWM Fault Condition Value (PWMMFAULTVAL)	360
23.4.24	PWM Interrupt Enable (PWMMINTEN)	363
23.4.25	PWMn Interrupt and Trigger Enable (PWMMnINTEN)	365
23.4.26	PWM Peripheral Properties (PWMMPP)	369
23.4.27	PWMn Fault Status 0 (PWMMnFLTSTAT0)	371

26.24 ADC (Add with Carry)	487
26.24.1 Example	487
26.25 SADD16 and SADD8 (Signed Add)	488
26.25.1 Example	488
26.26 SUB (Subtract)	489
26.26.1 Example	489
26.27 SBC (Subtract with Carry)	490
26.27.1 Example	490
26.28 RSB (Reverse Subtract)	490
26.28.1 Example	490
26.29 RSC (Reverse Subtract with Carry)	491
26.29.1 Example	491
26.30 SSUB16 and SSUB8 (Signed Subtract)	491
26.30.1 Example	491
26.31 MUL (Multiply)	492
26.31.1 Example	492
26.32 MLA (Multiply Accumulate)	492
26.32.1 Example	492
26.33 MLS (Multiply Subtract)	493

26.33.1 Example	493
26.34 UMULL (Unsigned Multiply Long)	493
26.34.1 Example	493
26.35 UMLAL (Unsigned Multiply Long with Accumulate)	494
26.35.1 Example	494
26.36 SMULL (Signed Multiply Long)	494
26.36.1 Example	494
26.37 SMLAL (Signed Multiply Long with Accumulate)	494
26.37.1 Example	494
26.38 UDIV (Unsigned Divide)	495
26.38.1 Example	495
26.39 AND (Bitwise AND)	495
26.39.1 Example	495
26.39.2 Example of forcing bits to 0	495
26.40 ORR (Bitwise OR)	496
26.40.1 Example	496
26.40.2 Example of forcing bits to 1	496
26.41 EOR (Exclusive OR, XOR)	497
26.41.1 Example	497
26.41.2 Example of flipping bits	497
26.42 BIC (Bit Clear)	498
26.42.1 Example	498
26.43 Shift operators	499
26.44 LSL (Logical Shift Left)	500
26.44.1 Example 1	500
26.44.2 Example 2	500
26.44.3 Example 3	500
26.45 LSR (Logical Shift Right)	501
26.45.1 Example	501
26.46 ASR (Arithmetic Shift Right)	502
26.46.1 Example	502
26.47 ROR (Rotate Right)	503
26.47.1 Example	503
26.48 RRX (Rotate Right Extended)	504
26.48.1 Example	504
26.49 B (Branch)	505
26.49.1 Example 1	505
26.49.2 Example 2	505
26.49.3 Example 3	505
26.50 BL (Branch with Link)	505
26.50.1 Example	505
26.51 BX and BXNS (Branch and Exchange, and Branch and Exchange Non-Secure)	506
26.51.1 Example 1	506
26.51.2 Example 2	506
26.52 ADR	506
26.52.1 Example	506
26.53 CMP (Compare)	507
26.53.1 Example	507
26.54 CMN (Compare Negative)	507

26.54.1 Example	507
26.55 TEQ (Test Equivalence)	508
26.55.1 Example	508
26.56 TST (Test bits)	508
26.56.1 Example	508
26.57 Vector floating point (VFP) operations	509
26.58 VLDR (Vector Load)	509
26.58.1 Example	509
26.59 VSTR (Vector Load)	510
26.59.1 Example	510
26.60 VMOV (Vector Move)	510
26.60.1 Example	510
26.61 VADD (Vector Add)	510
26.61.1 Example	510
26.62 Directives	511
26.63 Allocating memory to house instructions or data	511
26.63.1 Example	511
26.64 SETS	511
26.64.1 Example	511
26.65 EQU	511
26.65.1 Example	511
26.66 RN	512
26.66.1 Example	512
26.67 MACRO and MEND	512
26.67.1 Example 1	512
26.67.2 Example 2	513
26.68 AREA	513
26.68.1 Valid section attributes	513
26.68.2 Example	513
26.69 ENTRY and END	514
26.69.1 Example	514
26.70 DCB (Declare 8-bit bytes)	514
26.70.1 Example 1	514
26.70.2 Example 2	514
26.70.3 Example 3	514
26.71 DCW (Declare 16-bit half-words)	515
26.71.1 Example 1	515
26.71.2 Example 2	515
26.71.3 Example 3	515
26.72 DCD (Declare 32-bit words)	516
26.72.1 Example 1	516
26.72.2 Example 2	516
26.72.3 Example 3	516
26.73 ALIGN	517
26.73.1 Example 1	517
26.73.2 Example 2	517
26.74 SPACE	518
26.74.1 Example	518
26.75 FILL	518

26.75.1 Example	518
26.76 LTORG (Lookup table organised)	519
26.76.1 Example	519
26.77 EXPORT or GLOBAL	520
26.77.1 Example	520
26.78 IMPORT or EXTERN	520
26.78.1 Example	520
26.79 GET or INCLUDE	521
26.79.1 Example	521
26.80 Other directives offered by ARM Keil	521

1 Abbreviations

1.1 MCU

MCU stands for microcontroller.

1.2 ARM

ARM stands for Advanced RISC Machines.

1.3 RISC

RISC stands for Reduced Instruction Set Computer.

1.4 ISA

ISA stands for Instruction Set Architecture which is innate to all processors.

1.5 SVC

SVC stands for supervisor call instruction.

1.6 FIQ

FIQ stands for fast interrupt request.

1.7 DMA

DMA stands for direct memory access.

1.8 SPSR

SPSR stands for the saved program status register.

1.9 CPSR

CPSR stands for the current program status register.

1.10 SP

SP stands for the stack pointer.

1.11 LR

LR stands for the link register.

1.12 MMU

MMU stands for memory management unit.

1.13 MPU

MPU stands for memory protection unit.

1.14 AMBA

AMBA stands for advanced microcontroller bus architecture.

1.15 SoC

SoC stands for system-on-a-chip.

1.16 APB

APB stands for advanced peripheral bus.

1.17 AHB

AHB stands for advanced high-performance bus.

1.18 JTAG

JTAG stands for Joint Test Action Group.

1.19 RAM

RAM stands for random access memory.

1.20 CPU

CPU stands for central processing unit.

1.21 FET

FET stands for field effect transistor.

1.22 SRAM

SRAM stands for static RAM, or Static Random Access Memory.

1.23 DRAM

DRAM stands for dynamic RAM, or Dynamic Random Access Memory.

1.24 SLC

SLC stands for single level cell.

1.25 ALU

ALU stands for arithmetic logic unit.

1.26 APSR

APSR stands for application program status register.

1.27 EPSR

EPSR stands for execution program status register.

1.28 IPSR

IPSR stands for interrupt program status register.

1.29 I/O

I/O stands for input and output.

1.30 NVIC

NVIC stands for nested vectored interrupt controller.

1.31 SysTick

SysTick stands for system tick timer.

1.32 Opcode

Opcode stands for operation code.

1.33 MSB

MSB stands for most significant bit.

1.34 LSB

LSB stands for least significant bit.

1.35 VFP

VFP stands for vector floating point.

1.36 FPU

FPU stands for floating point unit.

1.37 MPU

MPU stands for multicore processing unit.

1.38 GiB

GiB stands for gibibyte.

1.39 IDE

IDE stands for integrated development environment.

1.40 I/O or IO

I/O or IO stands for input/output.

1.41 GPIO

GPIO stands for general purpose input/output.

1.42 ADC

ADC stands for analogue to digital converter.

1.43 PWM

PWM stands for pulse width modulation.

1.44 UART

UART stands for universal asynchronous receiver/transmitter.

1.45 DTE

DTE stands for data terminal equipment.

1.46 DCE

DCE stands for data communication equipment.

1.47 TX or Tx

TX or Tx stands for transmitting.

1.48 RX or Rx

RX or Rx stands for receiving.

1.49 GND

GND stands for ground.

1.50 BRD

BRD stands for baud-rate divider.

1.51 TTL

TTL stands for transistor-transistor logic.

1.52 RTOS

RTOS stands for real time operating system.

1.53 IRQ

IRQ stands for interrupt request.

1.54 ISR

ISR stands for interrupt service routine.

2 Definitions

2.1 Microprocessor system

A microprocessor system is a system which is built on top of logic devices that can:

- Undertake arithmetic operations
- Undertake logic operations
- Interface with external devices

2.2 Word

A word is a 2 byte (16-bit) value.

2.3 Using I/O modules

- Configure control registers
- Clear or monitor status registers
- Read or write data registers
- Instructions:
 - ▶ `MOV <address of destination>, <source of value>`
Move instruction, which copies the value from the source to the destination.
 - ▶ `LDR <address of destination>, <source of value>`
Load register instruction, which loads a value from a memory address into a register.
 - ▶ `STR <address of destination>, <source of value>`
Store instruction, which stores a value from a register to a memory address.

2.4 Bits and bytes

- 8 bits are called a byte.
- 16 bits of 2 bytes are called a half-word.
- 32 bits or 4 bytes are called a word.
- 64 bits or 8 bytes are called a double-word.

2.5 Fast interrupt request (FIQ)

An fast interrupt request (FIQ) is a higher priority interrupt request, that is prioritised by disabling interrupt request (IRQ) and other fast interrupt request handlers during request servicing. Therefore, no other interrupts can occur during the processing of the active FIQ interrupt.

2.6 Direct memory access (DMA)

Direct memory access (DMA) is a feature of microprocessor systems that allows certain hardware subsystems to access main system memory such as RAM (Random Access Memory) independently of the central processing unit (CPU).

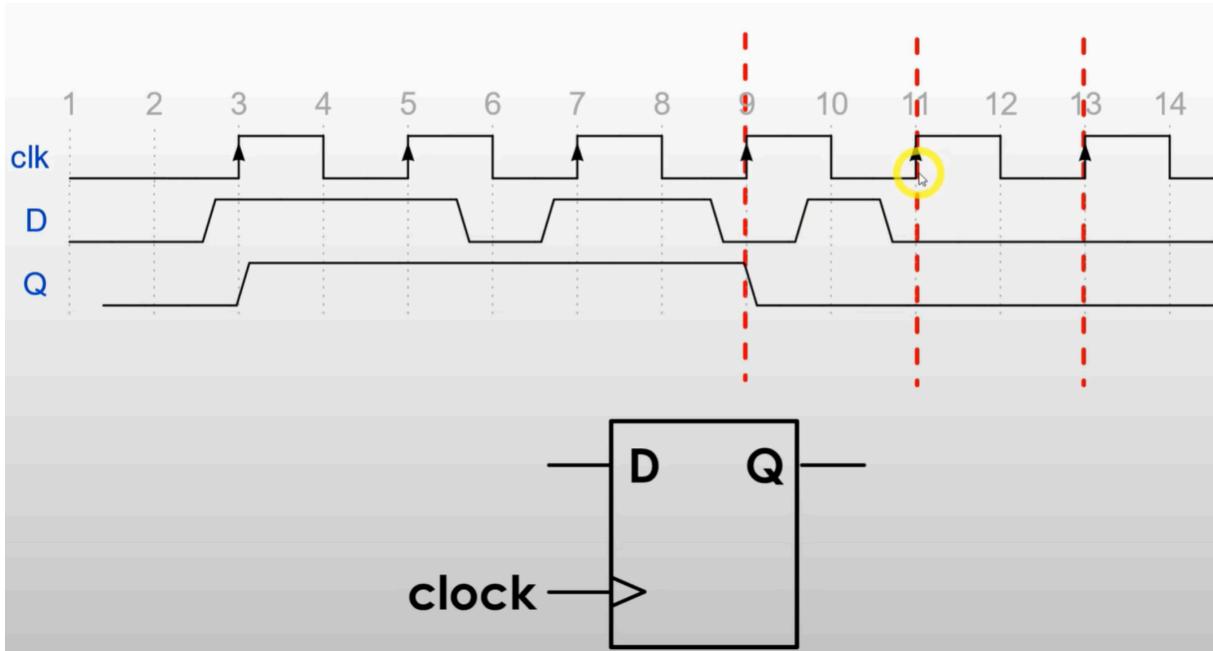

2.7 Truth table

A truth table maps the all the possible inputs to the outputs. Below is truth table of an inverter.

Input	Output
1	0
0	1

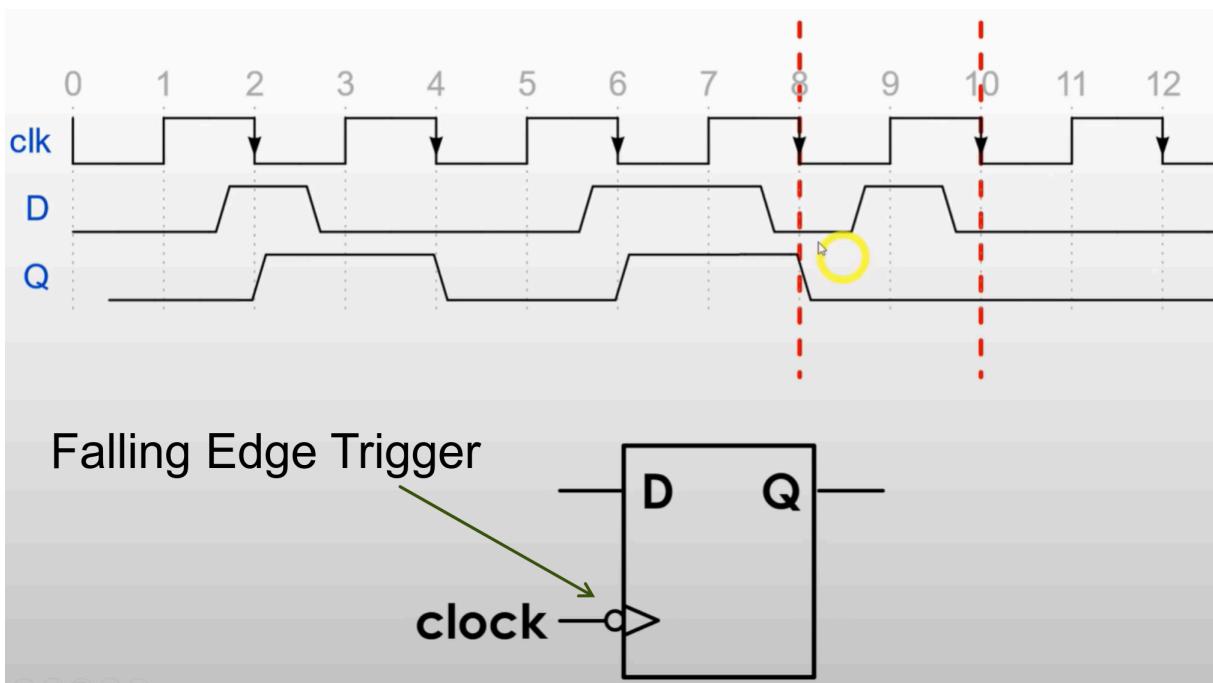

2.8 Rising edge

- A rising edge is when the input transitions from 0 to 1.
- A transistor, if not notated, is usually sensitive to the rising edge as shown below.

2.9 Falling edge

- A falling edge is when the input transitions from 1 to 0.
- A transistor sensitive to the falling edge is notated using a small circle at the input of the transistor, as shown below.

2.10 Bus

- A bus is essentially a **data highway** that transfers data between components inside a computer or between computers.
- It encompasses both hardware, like wires, optical fibre, and software, including communication protocols.

2.10.1 Address bus

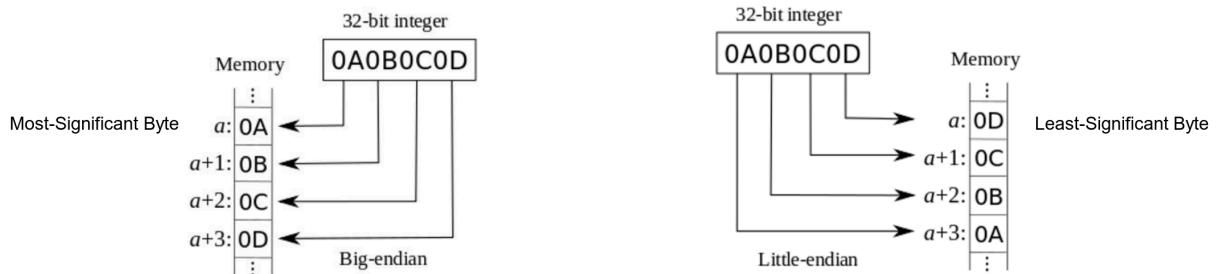

- An address bus is a bus that is used to specify a physical address.
- When a processor or DMA-enabled device needs to read or write to a memory location, it specifies that memory location on the address bus.
- The width of the address bus determines the amount of memory a system can address.
- For example, a system with a 32-bit address bus can address 2^{32} memory locations.
- If each memory location holds one byte, the addressable memory space is about 4 GB.

2.10.2 Data bus

- A data bus is a bus that transfers data between different components inside a computer or between computers.
- The amount of bytes a memory unit can read or write is dependent on the number of lines of the data bus, rather than the address bus.

2.11 Endianness of memory

- **Endianness** is the ordering or sequencing of bytes of a word of digital data in computer memory storage or during transmission.
- Words may be represented in **big-endian** or **little-endian** manner.
- **Big-endian** systems store the **most-significant** byte of a word at the **smallest** memory address and the **least-significant** byte at the **largest**.
- **Little-endian** systems store the **least-significant** byte of a word at the **smallest** memory address and the **most-significant** byte at the **largest**.

2.12 Base address

The base address is a common reference for a series of related addresses.

2.13 Address offset

The address of set is an individual offset from a common reference address.

2.14 Address indexing

Address indexing refers to the operation of adding an offset to a base address.

$$\text{Address indexing} = \text{Base address} + \text{Offset} = [\text{Base address}, \text{offset}]$$

2.15 Configuration register

A configuration register is a register with programmable switches.

2.16 Maskable data register

A maskable data register is a data register that has a pin selection mask.

2.16.1 Example

- GPIO_PORTF_DIR_R EQU 0x40025 400 is the GPIO direction (input or output).
- GPIO_PORTF_AFSEL_R EQU 0x40025 420 is the GPIO alternate function select.
- GPIO_PORTF_PUR_R EQU 0x40025 510 is the GPIO pull up select (whether to enable the pull-up resistors or not).
- GPIO_PORTF_DEN_R EQU 0x40025 51C is the GPIO digital enable.
- GPIO_PORTF_AMSEL_R EQU 0x40025 528 is the GPIO analogue mode select.
- GPIO_PORTF_PCTL_R EQU 0x40025 52C is the GPIO port control.
- PF1 EQU 0x40025 008 is the GPIO “port” address.
- PF2 EQU 0x40025 010 is the GPIO “port” address.
- PF3 EQU 0x40025 020 is the GPIO “port” address.
- PF4 EQU 0x40025 040 is the GPIO “port” address.
- PFA EQU 0x40025 038 is the address of 3 ports, PF1 - PF3.
- SYSCTL_RCGCGPIO_R EQU 0x400FE608 is the run mode clock gating control.

2.16.2 Why have maskable data registers?

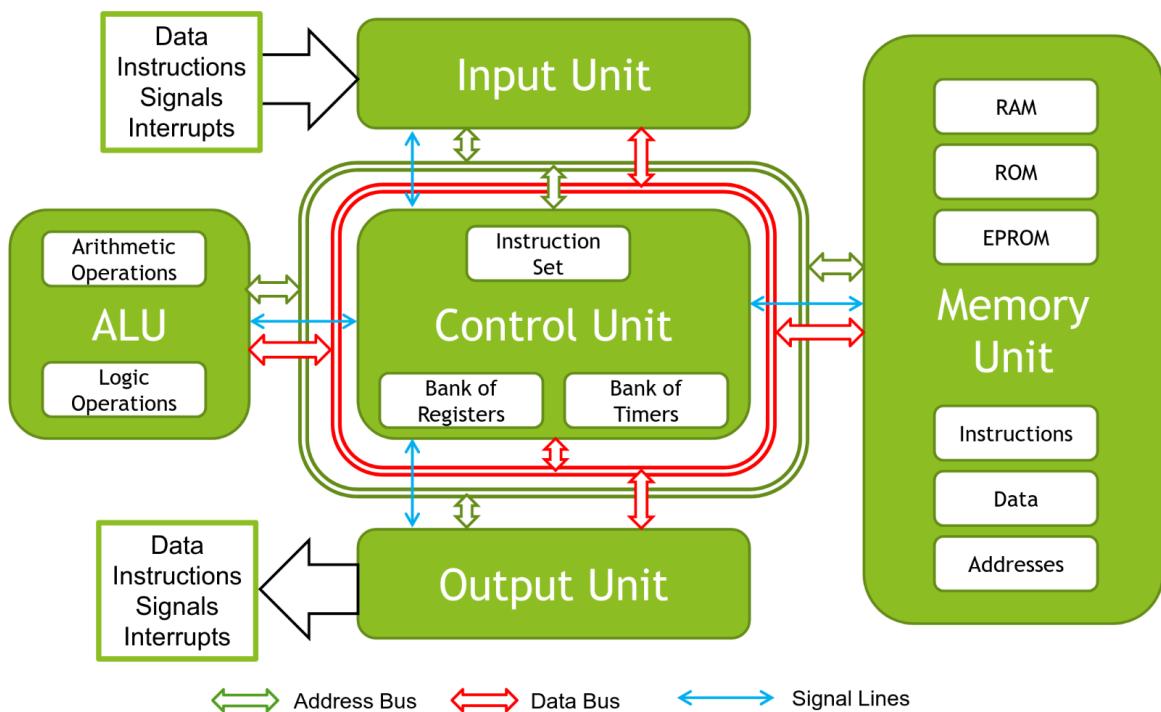

1. Security in control, to avoid situations where the intention is to turn on one motor, but several other motors have been turned on instead.
2. Security in communication, to stop others from interpreting the intercepted data in a communication. This is possible because intercepted data is not filtered by any specific mask, and received data is filtered by a specific mask.

3 Basics of brains

3.1 Characteristics of the human brain

- Able to memorise past, present and future.
- Able to capture input data.
- Able to undertake operations with numbers or symbols.
- Able to produce output data.
- Able to control mental operations.
- Able to control physical actions.
- Able to communicate.
- Able to learn human languages.
- Able to learn machine languages.
- Able to learn new knowledge and new skills.

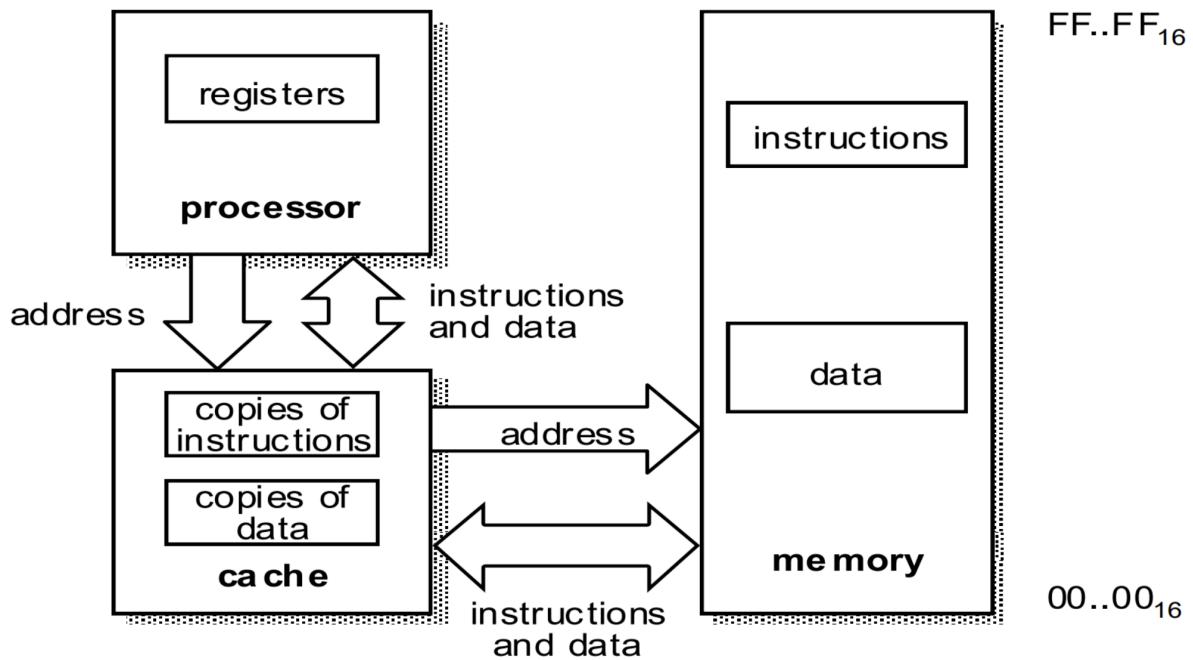

3.2 Blueprint of a machine brain

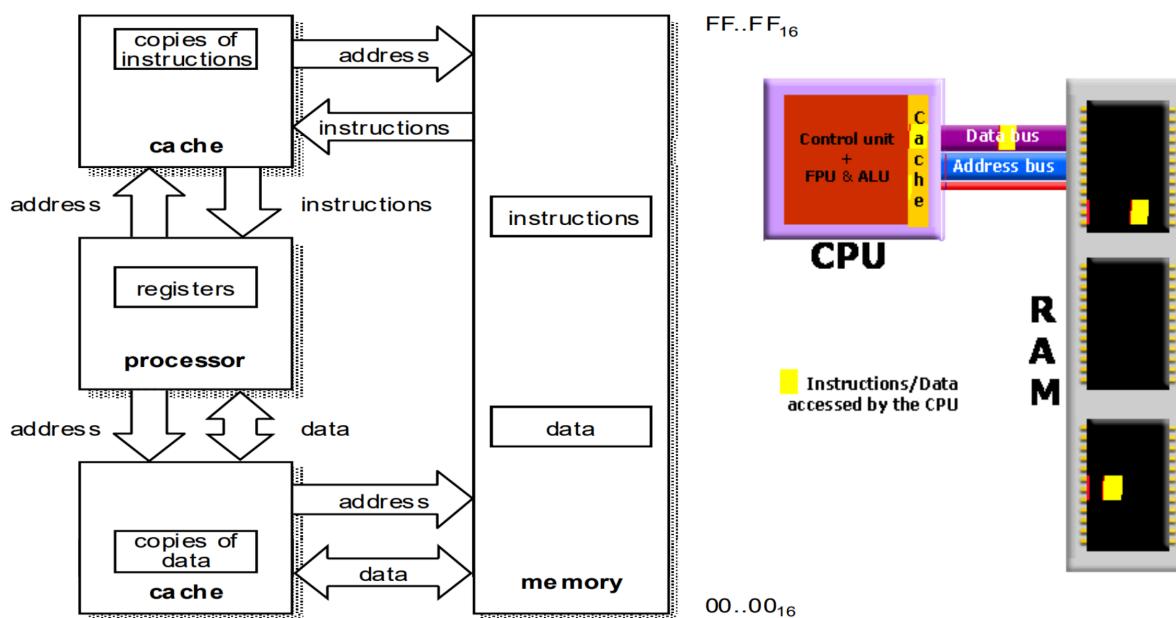

3.3 Characteristics of a machine brain

- Able to memorise data (to use) and instructions (to do)
- Able to capture input data.
- Able to undertake arithmetics operations with numbers.
- Able to undertake logic operations with numbers and symbols.
- Able to produce output data.
- Able to control mental operations.
- Able to control physical actions.
- Able to communicate.
- Able to learn human languages in the future.
- Able to learn machine languages in the future.
- Able to learn new knowledge and new skills in the future.

3.4 Van Neumann architecture

3.5 Harvard architecture

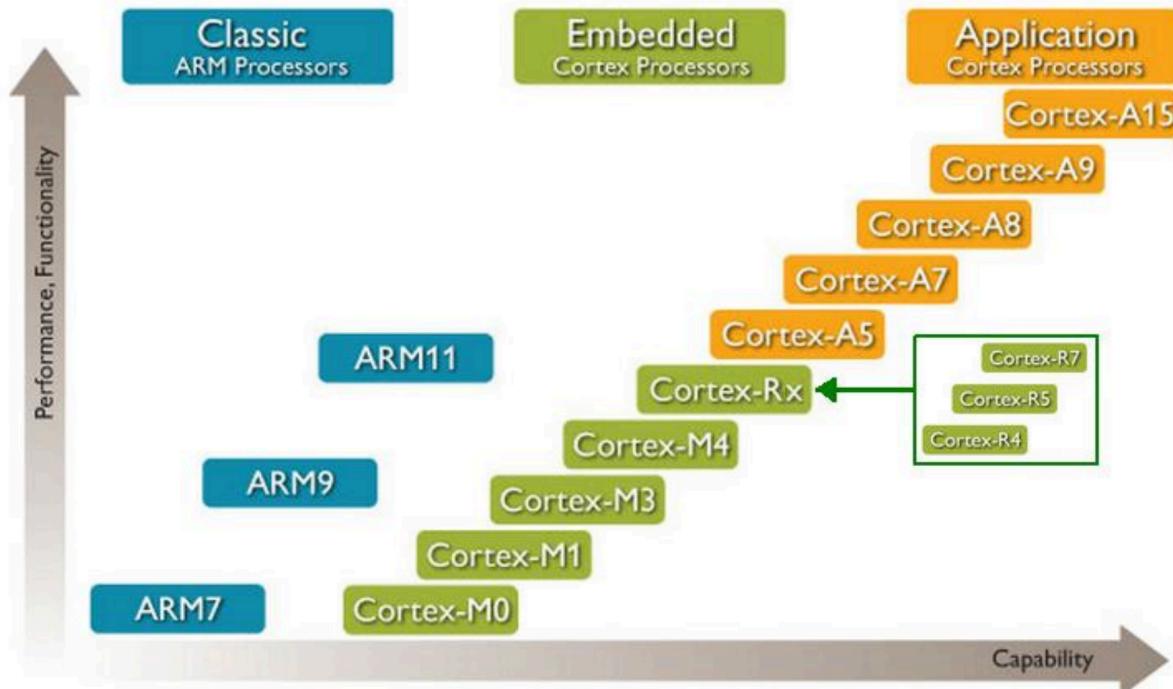

4 ARM: Advanced RISC Machines

- ARM Ltd was founded in 1990
- ARM Ltd is headquartered in Cambridge, UK

4.1 ARM Family

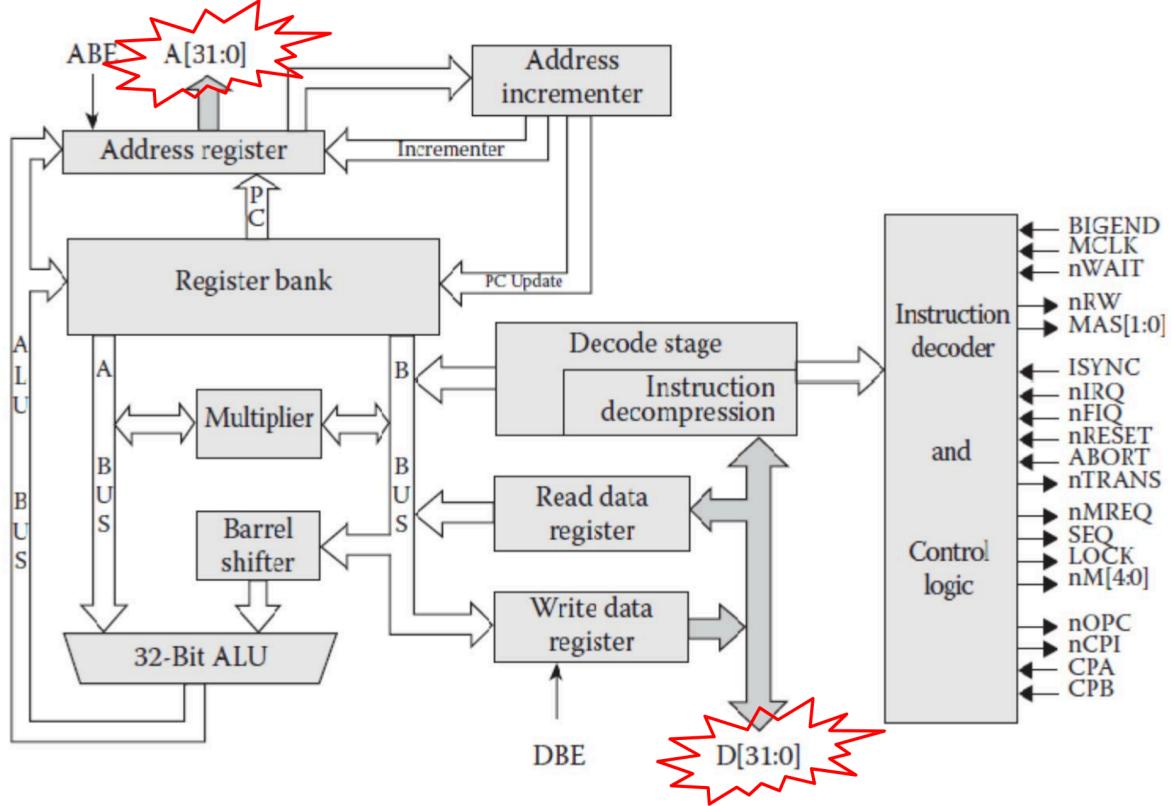

- Cortex-M Series: For microcontroller applications
- Cortex-R Series: For real-time applications
- Cortex-A Series: For advanced applications

4.2 ARM Cortex uses the RISC architecture

- ARM uses the RISC architecture.
 - ISA stands for Instruction Set Architecture which is innate.
 - RISC stands for Reduced Instruction Set Computer.
 - Most instructions execute in a single cycle.
 - ARM instruction set is 32-bit.
 - Thumb instruction set is 16 or 32-bit.
- ARM is a 32-bit load-store architecture.
 - 8 bits are called a byte.
 - 16 bits of 2 bytes are called a half-word.
 - 32 bits or 4 bytes are called a word.
 - 64 bits or 8 bytes are called a double-word.
 - The only memory accesses are loads and stores.

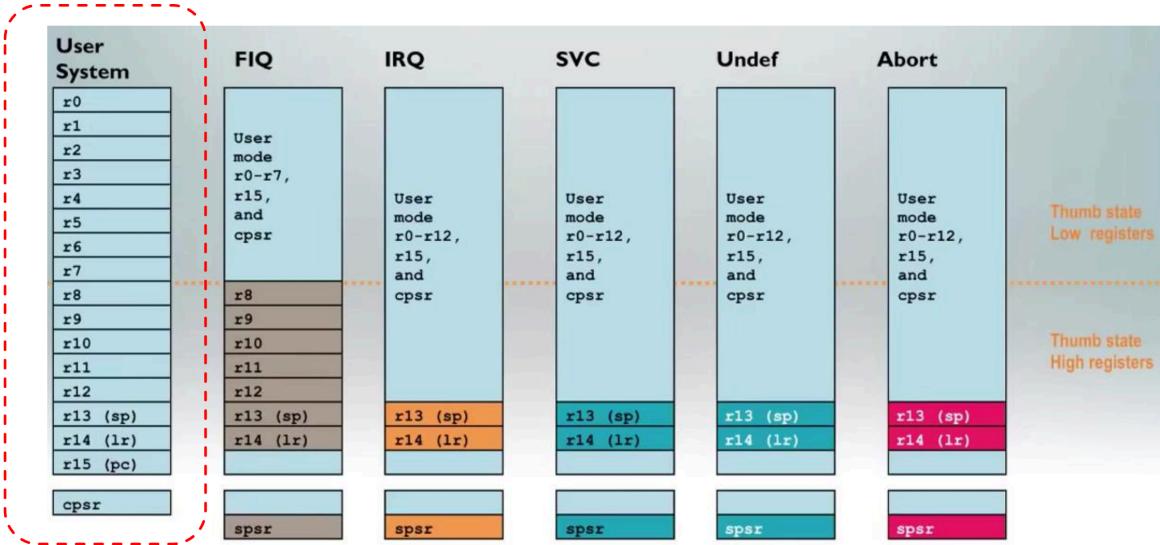

4.2.1 Architecture of the ARM7TDMI Processor

4.3 Modes in ARM Cortex

- **Supervisor (SVC):** Entered on reset and when a Supervisor call instruction (SVC) is executed. Privileged and exception mode.
- **FIQ:** Entered when a high priority (fast) interrupt is raised. Privileged and exception mode.
- **IRQ:** Entered when a normal priority interrupt is raised. Privileged and exception mode.
- **Abort:** Used to handle memory access violations. Privileged and exception mode.
- **Undef:** Used to handle undefined instructions. Privileged and exception mode.
- **System:** Privileged mode using the same registers as User mode.
- **User:** Mode under which most applications and operating system tasks run. Unprivileged mode.

4.4 Registers in ARM Cortex

Where:

- “SPSR” is the saved program status register
- “CPSR” is the current program status register
- “SP” is the stack pointer
- “LR” is the link register

Note that the system mode uses the user mode register set.

4.4.1 Register table

User/System	Supervisor	Abort	Undefined	Interrupt	Fast interrupt
R0	R0	R0	R0	R0	R0
R1	R1	R1	R1	R1	R1
R2	R2	R2	R2	R2	R2
R3	R3	R3	R3	R3	R3
R4	R4	R4	R4	R4	R4
R5	R5	R5	R5	R5	R5
R6	R6	R6	R6	R6	R6
R7	R7	R7	R7	R7	R7
R8	R8	R8	R8	R8	R8_FIQ

R11	R11	R11	R11	R11	R11_FIQ
R12	R12	R12	R12	R12	R12_FIQ
R13	R13_SVC	R13_ABORT	R13_UNDEF	R13_IRQ	R13_FIQ
R14	R14_SVC	R14_ABORT	R14_UNDEF	R14_IRQ	R14_FIQ
PC	PC	PC	PC	PC	PC

CPSR	CPSR	CPSR	CPSR	CPSR	CPSR
SPSR_SVC	SPSR_ABORT	SPSR_UNDEF	SPSR_IRQ	SPSR_FIQ	

= banked register

4.4.2 Current program status register (CPSR, R16)

31	30	29	28	27	26	25	24	23	20	19	16	15	10	9	8	7	6	5	4	0
N	Z	C	V	Q	Res	J	RESERVED	GE[3:0]	RESERVED	E	A	I	F	T	M[4:0]					

Where GE stands for greater than or equal status flags.

Overview:

Field	Description	Architecture
N Z C V	Condition code flags	All
J	Jazelle state flag	5TEJ and above
GE[3:0]	SIMD condition flags	6
E	Endian load/store	6
A	Imprecise abort mask	6
I	IRQ interrupt mask	All
F	FIQ interrupt mask	All
T	Thumb state flag	4T and above
Mode[4:0]	Processor mode	All

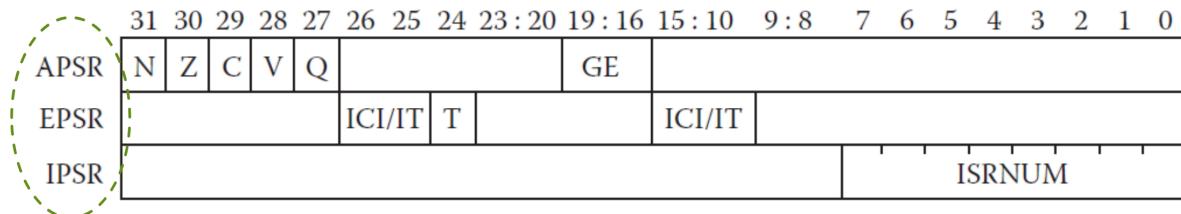

Flag field	Description
N	Negative result from the ALU
Z	Zero result from the ALU
C	ALU operation caused carry
V	ALU operation overflowed
Q	ALU operation saturated
J	Java byte code execution

,

Control bits	Description
I	1: Disables IRQ
F	1: Disables FIQ
T	1: Thumb, 0: ARM

Mode bits	Description
0b10000	User
0b11111	System
0b10001	FIQ
0b10010	IRQ
0b10011	SVC (Supervisor)
0b10111	Abort
0b11011	Undefined

4.4.3 Cortex M4's status register

Where:

- APSR stands for application program status register
- EPSR stands for execution program status register
- IPSR stands for interrupt program status register

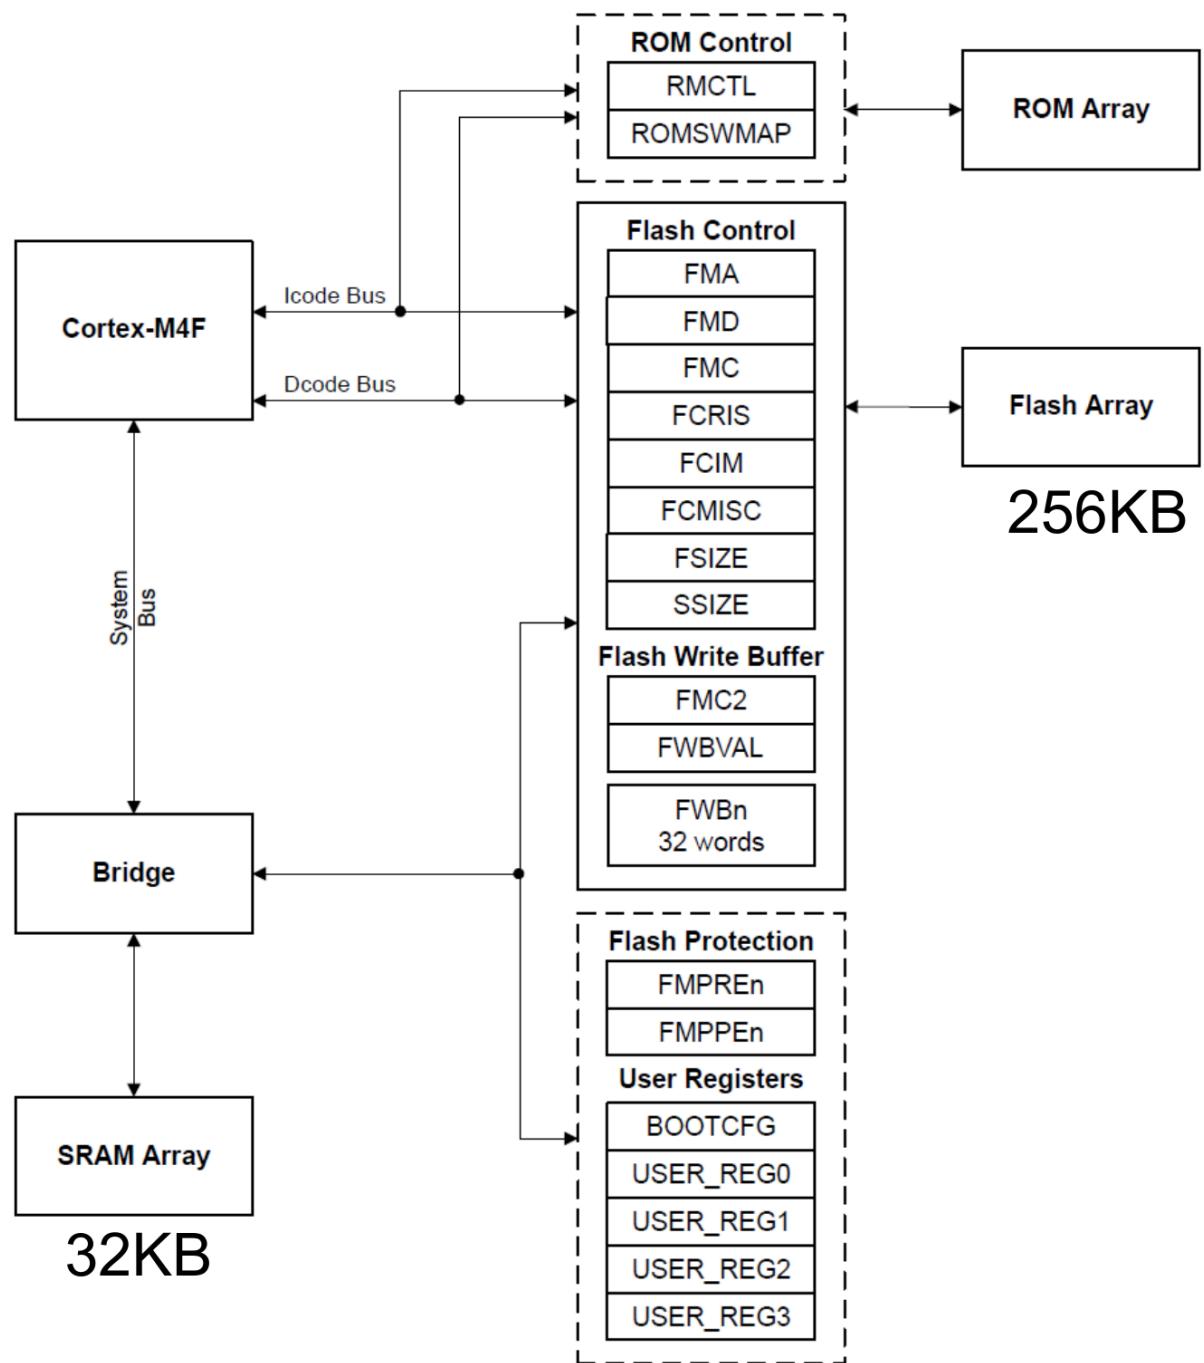

4.5 ARM Cortex as a microcontroller

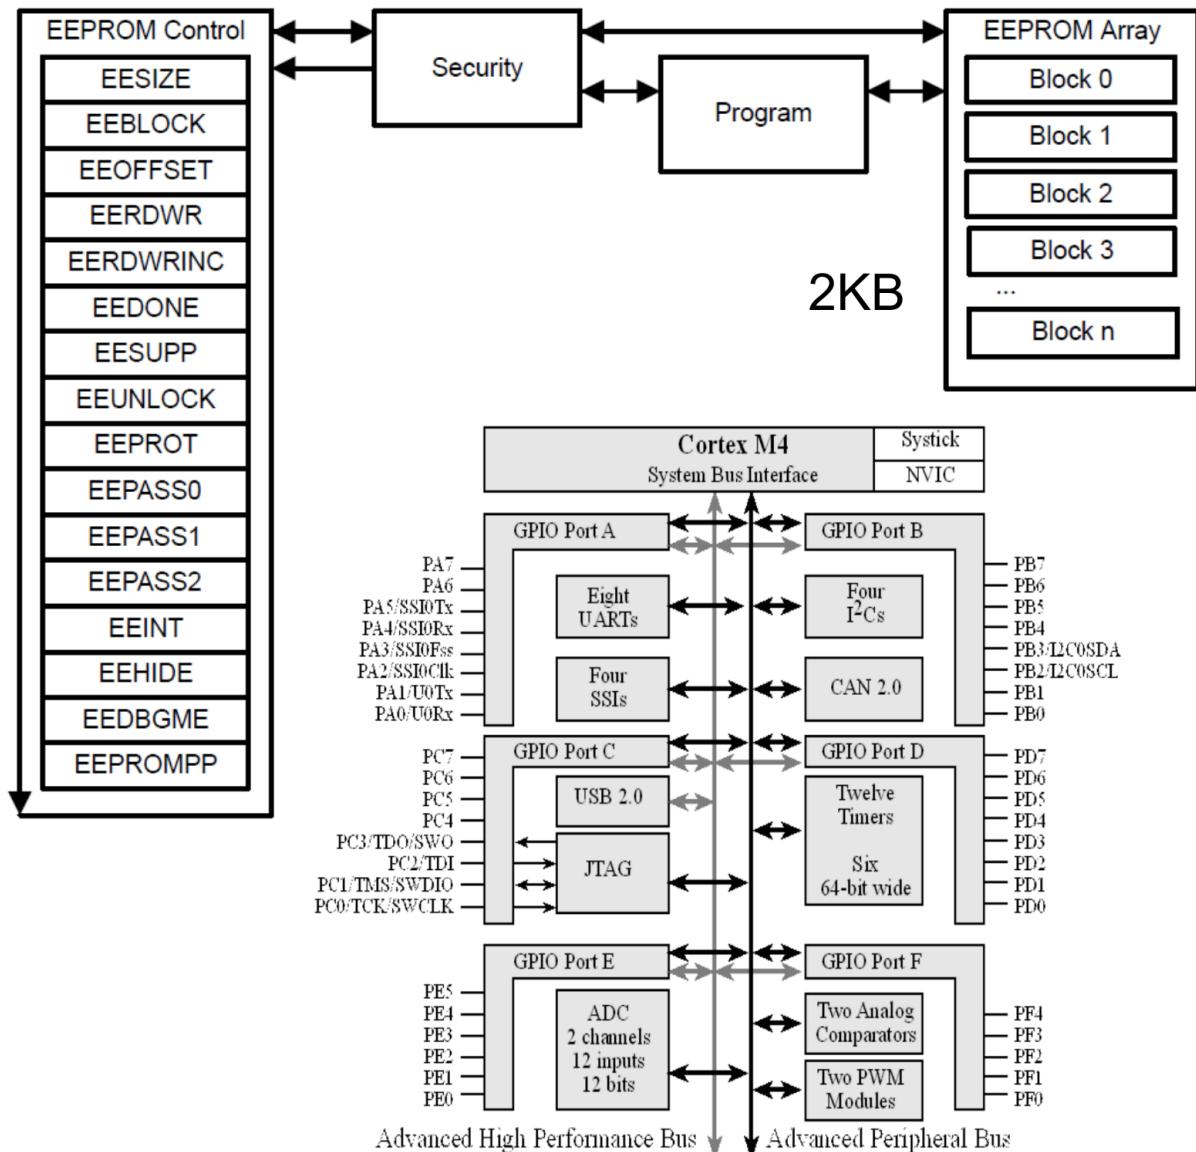

- ARM supports application profile.
 - Memory Management Unit (MMU).
 - Highest performance at lowest power consumption.
 - Trust zone for a safe and extensible system.
- ARM supports real-time profile
 - Memory Protection Unit (MPU).
 - Low latency and predictability of real-time needs.
 - Tightly coupled memory for fast and deterministic access.
- ARM supports microcontroller profile
 - Lowest gate count entry point.
 - Deterministic and predictable behaviour.
 - Deeply embedded use.

4.6 ARM features

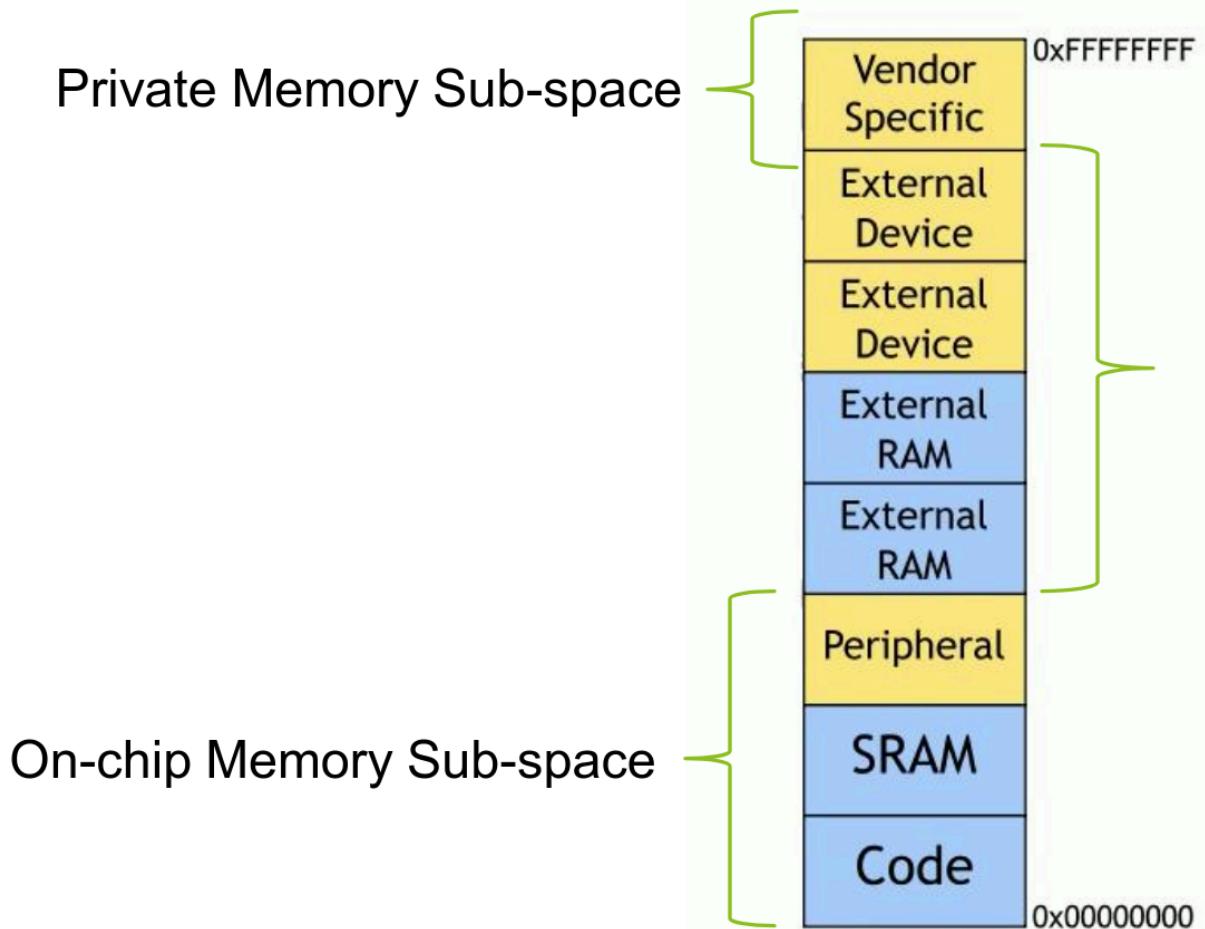

- ARM has two internal buses.
 - The ARM Advanced Microcontroller Bus Architecture (AMBA) is an open-standard, on-chip interconnect specification for the connection and management of functional blocks in system-on-a-chip (SoC) designs. It facilitates development of multiprocessor designs with large numbers of controllers and peripherals.
- ARM Cortex supports direct memory access.
- ARM Cortex includes debug port.
 - JTAG (Joint Test Action Group) specifies the use of a dedicated debug port implemented a serial communication interface for low-overhead access without requiring direct external access to the system address and data buses.

4.7 Memory inside TM4C123G

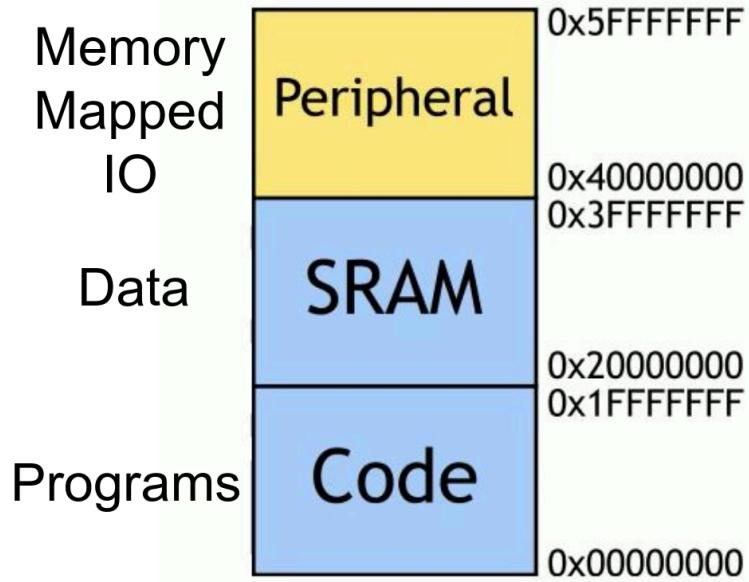

4.8 ARM Cortex M's memory space

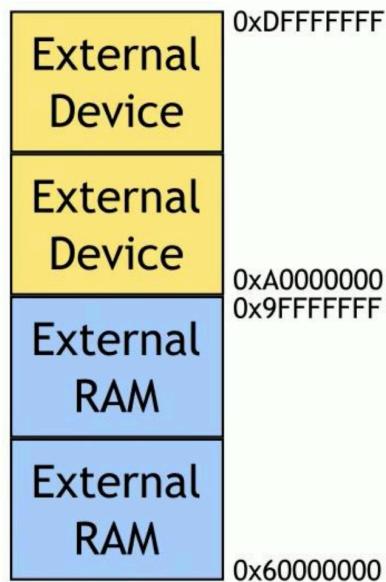

- 32-bit addresses support 4 GiB memory space.
- Code, data and I/O share the same memory space.
- Data types are **bytes**, **half-words**, and **words**.
- Predefined regions have distinct characteristics.
 - Executable
 - Device or strongly-ordered
 - Shareable

4.8.1 On-chip memory subspace

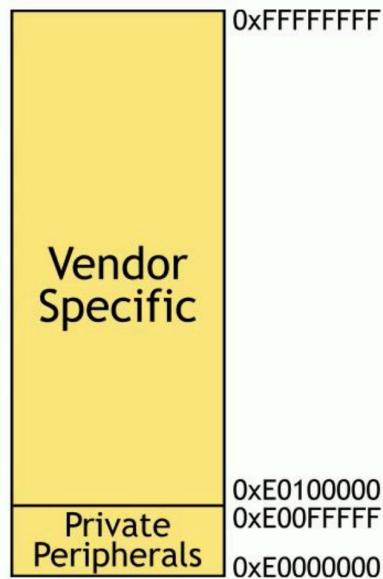

- On-chip code, data and I/O are located in the first 1.5 GiB of memory space.
- Each is allocated 0.5 GiB.
- May use physically separate buses for each space.

4.8.2 Off-chip memory subspace

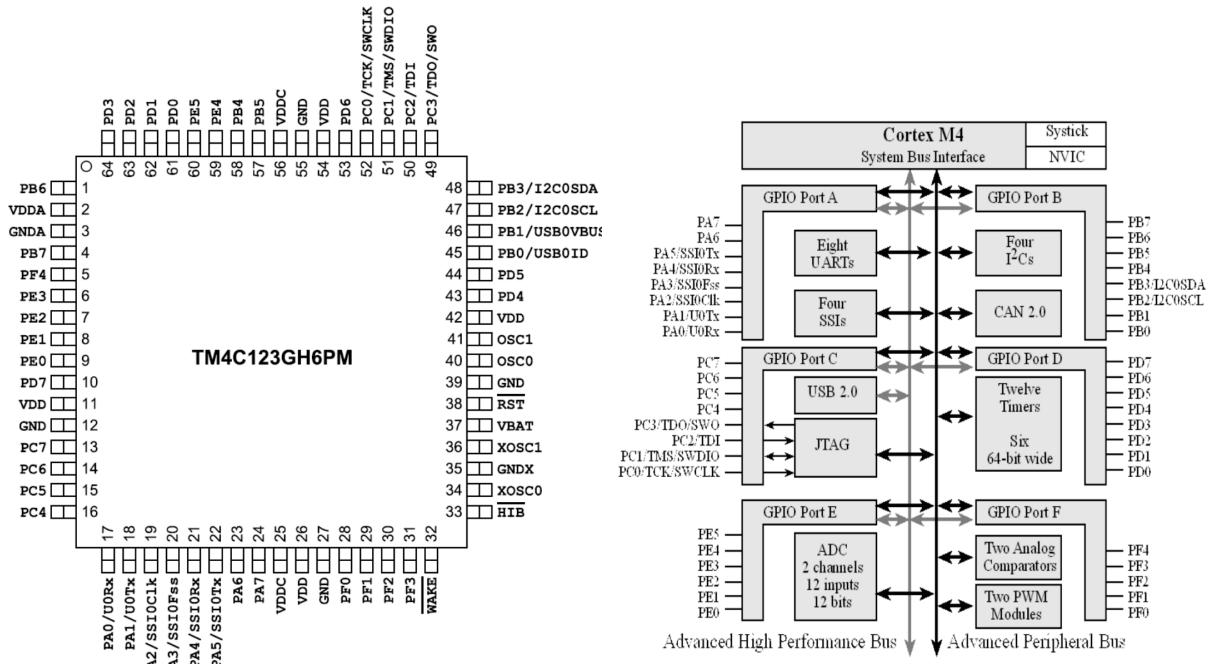

- 1 GiB reserved for each of off-chip data and off-chip devices.
- Off-chip memory bus requires many pins.
- Off-chip memory access time is usually slower and uses more power.

4.8.3 Private memory subspace

- Private peripheral bus occupies 1 MiB of space.
- Registers that control peripherals that are a mandatory part of the Cortex M architecture are mapped here.
 - Nested vectored interrupt controller (NVIC)
 - System tick timer (SysTick)
 - Fault status and control
 - Processor debugging

4.9 Cortex M4 pin diagram

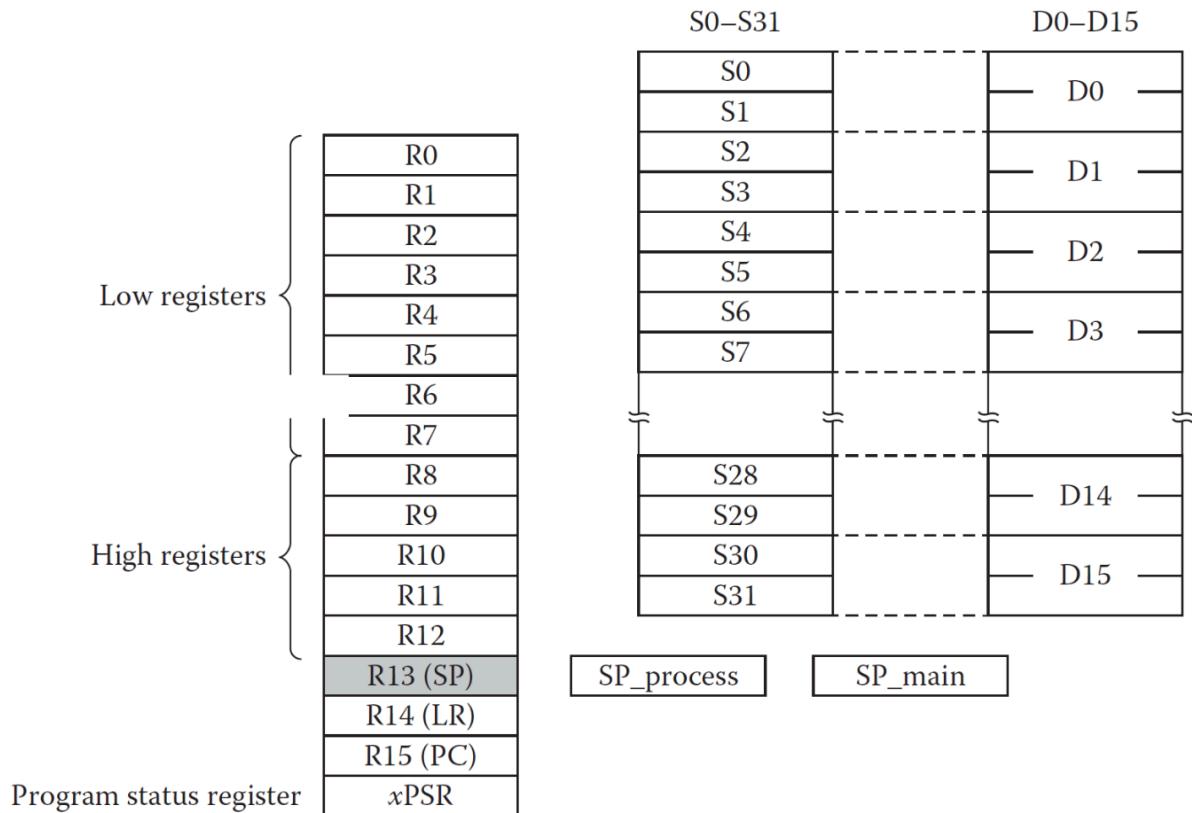

4.10 Cortex M4 table of pin usage

IO	Pin	Analog Function	Digital Function (GPIO PCTL PMCx Bit Field Encoding) ^a

4.11 Cortex M4's floating point unit's registers

5 Typical types of application software

6 Binary logic devices

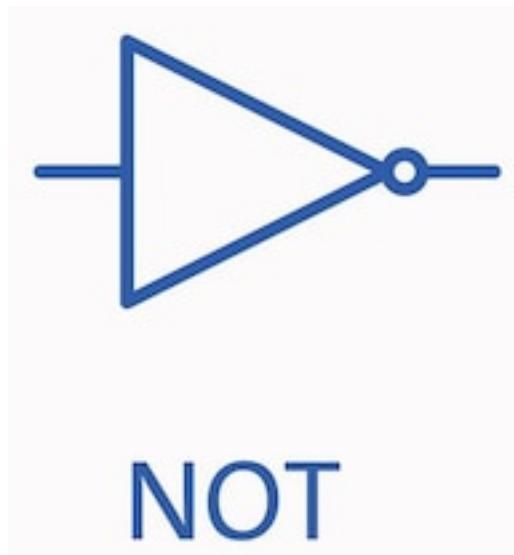

6.1 Binary number systems

Binary values	Implementation
1 (logic high)	+5 V (logic high)
0 (logic low)	0 V (logic low)

6.2 Binary logic operations

Operation	Boolean expressions				
NOT	A'	$\neg A$	\bar{A}	$\neg A$	
AND	AB	A^*B	$A \cdot B$	$A \wedge B$	$A \cap B$
OR	$A + B$	$A \vee B$	$A \cup B$		
NAND	$(AB)'$	\overline{AB}			
NOR	$(A + B)'$	$\overline{A + B}$			
XOR	$A \oplus B$	$A @ B$			
XNOR	$(A \oplus B)'$	$\overline{A \oplus B}$	$(A @ B)'$	$\overline{A @ B}$	

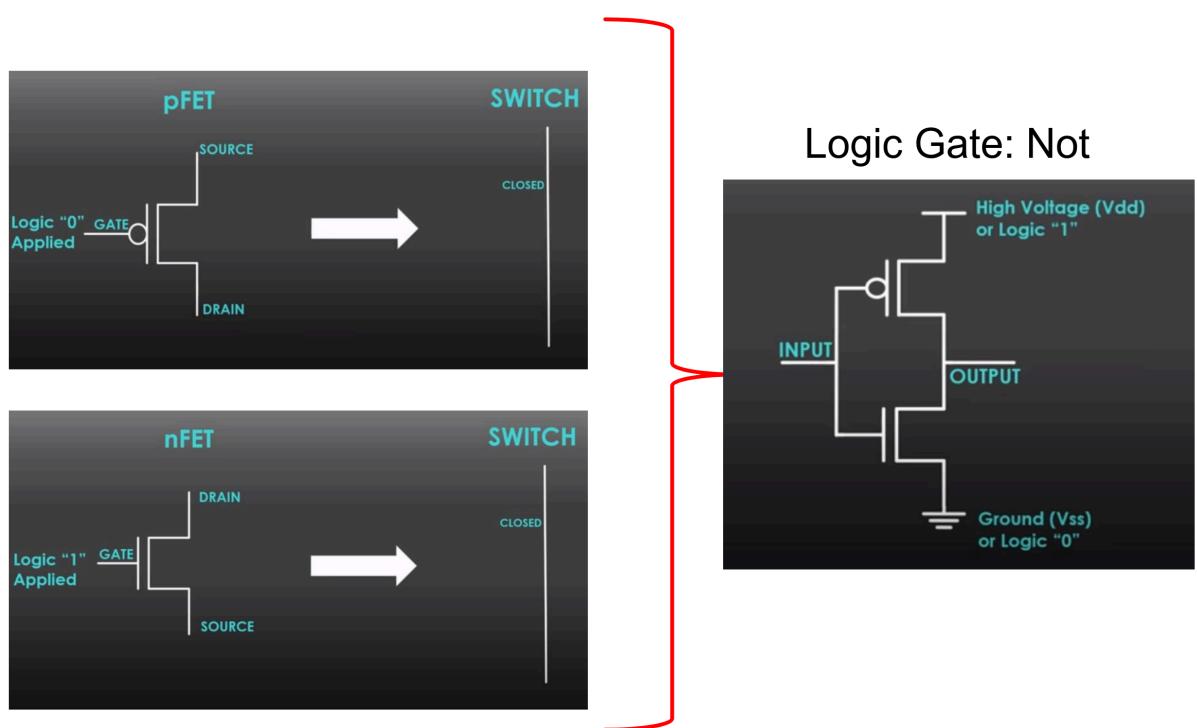

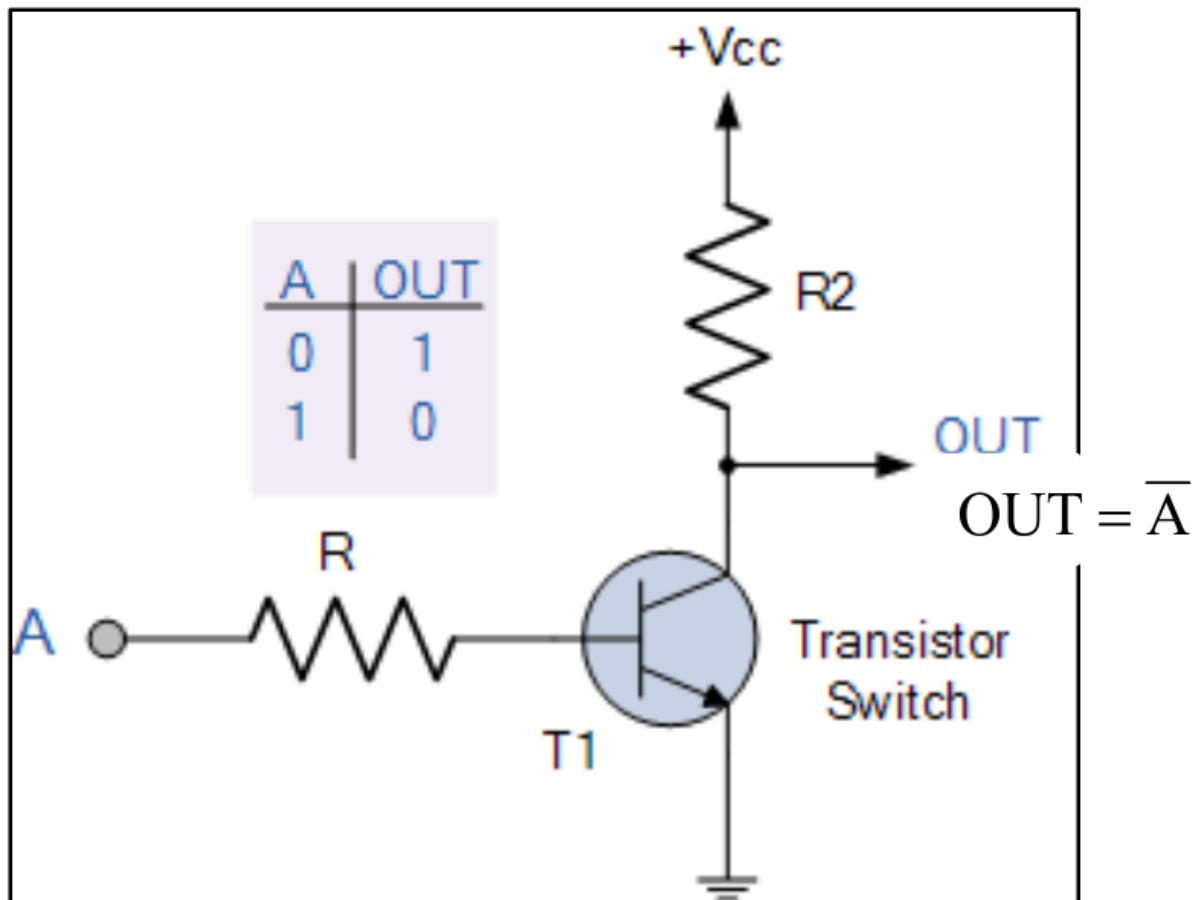

6.3 NOT logic gate

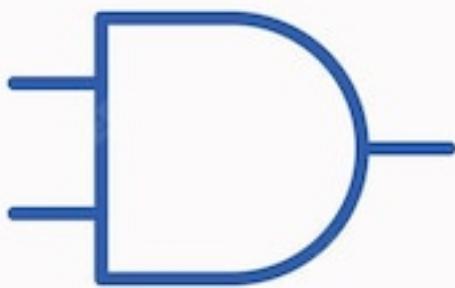

6.3.1 Truth table

Input (A)	Output (\bar{A})
1	0
0	1

6.3.2 Circuit diagrams

6.4 AND logic gate

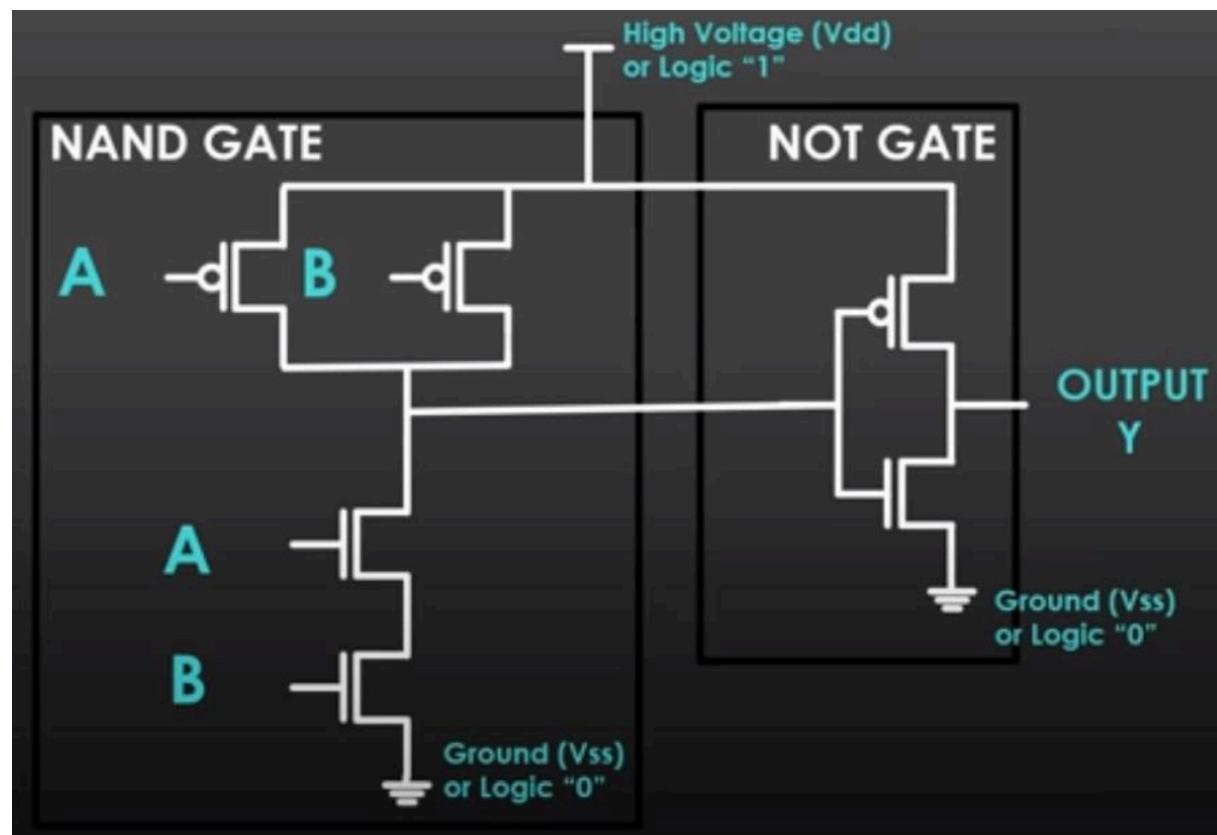

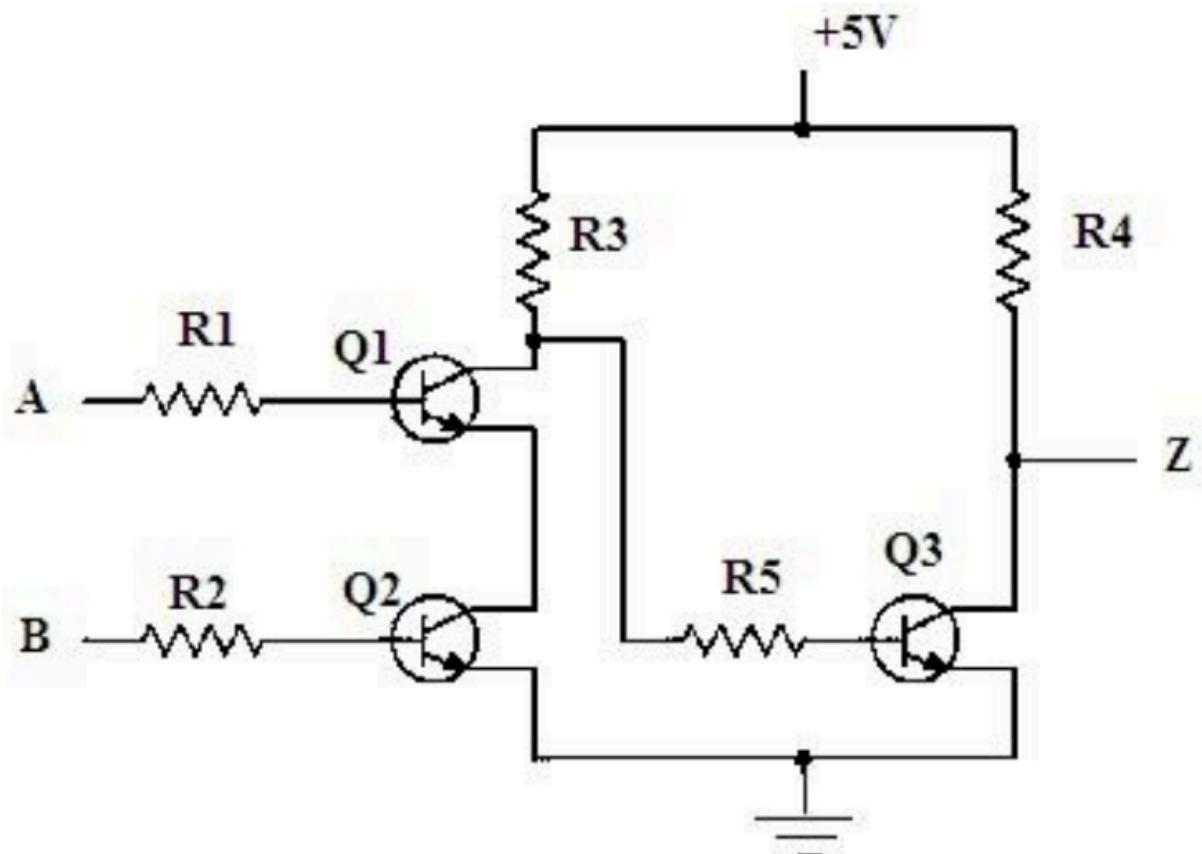

AND

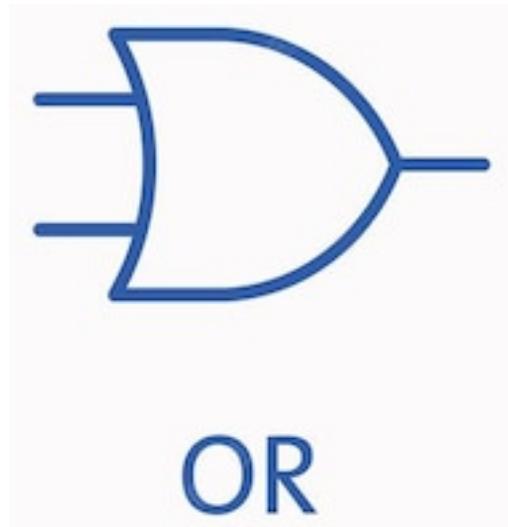

6.4.1 Truth table

Input 1 (X)	Input 2 (Y)	Output ($X \cdot Y$)
0	0	0
0	1	0
1	0	0
1	1	1

6.4.2 Circuit diagrams

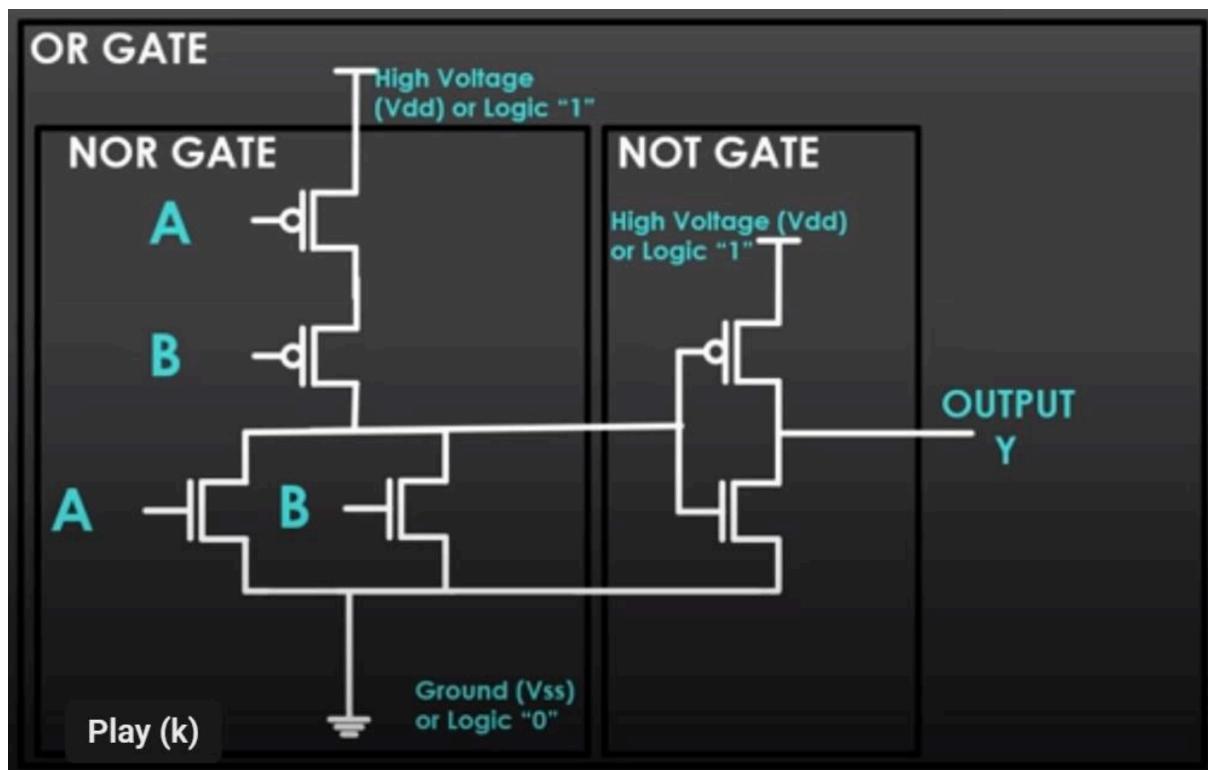

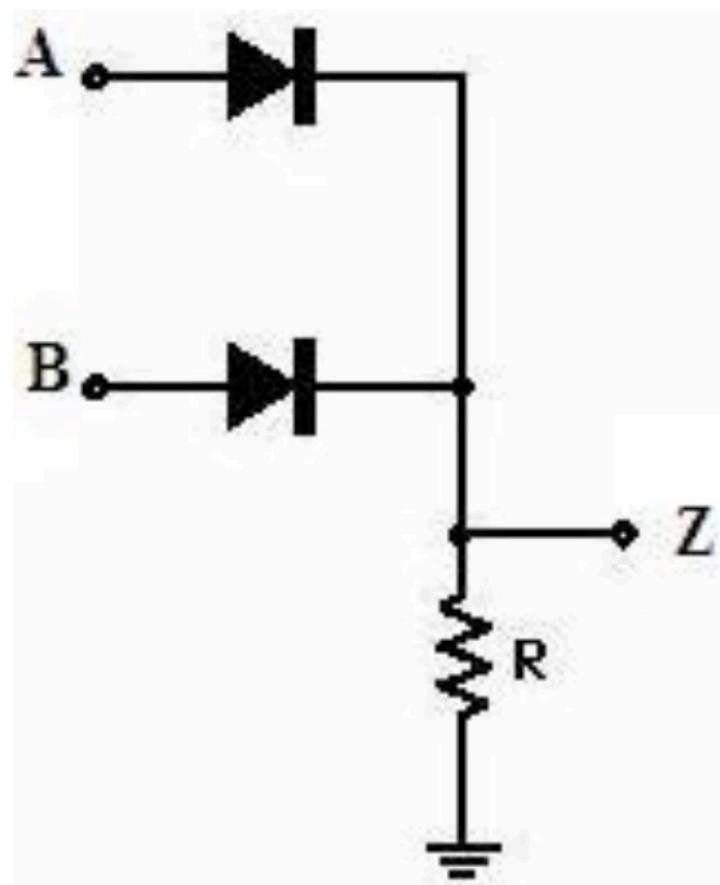

6.5 OR logic gate

6.5.1 Truth table

Input 1 (X)	Input 2 (Y)	Output ($X + Y$)
0	0	0
0	1	1
1	0	1
1	1	1

6.5.2 Circuit diagrams

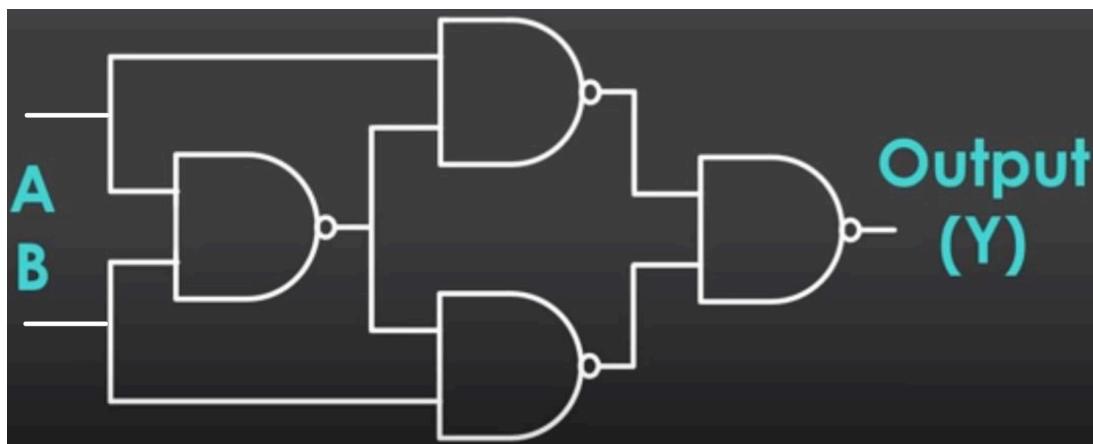

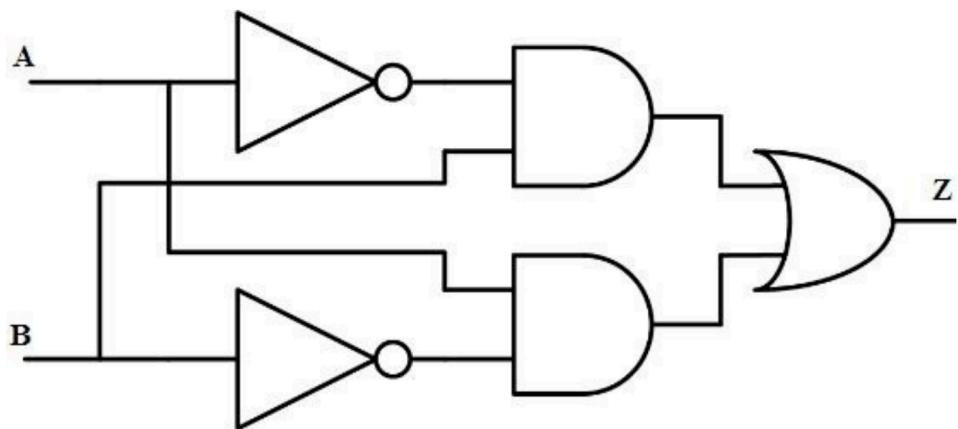

6.6 XOR logic gate

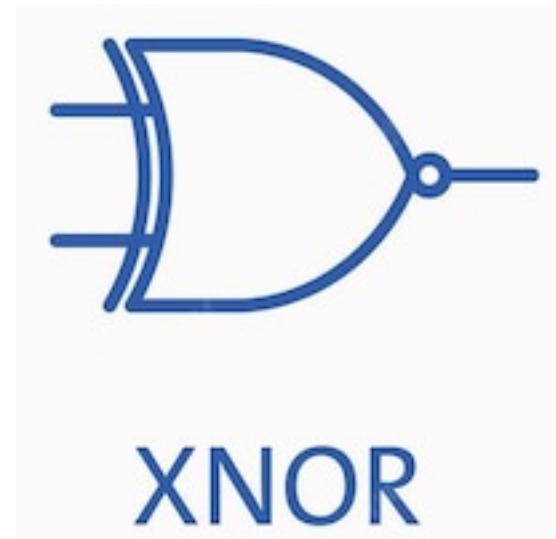

6.6.1 Truth table

Input 1 (X)	Input 2 (Y)	Output ($X \oplus Y$)
0	0	0
0	1	1
1	0	1
1	1	0

6.6.2 Circuit diagrams

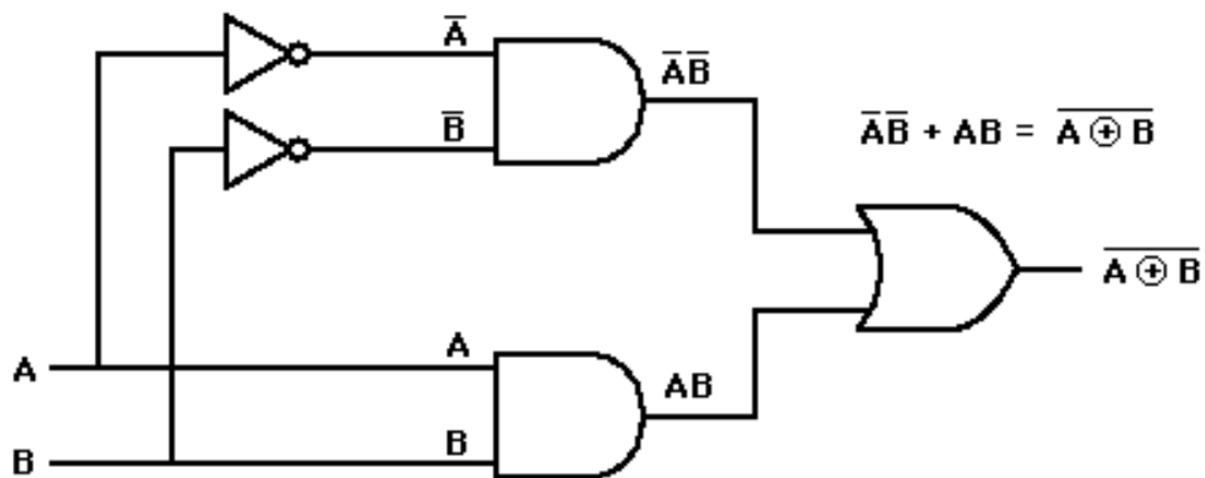

6.7 XNOR logic gate

6.7.1 Truth table

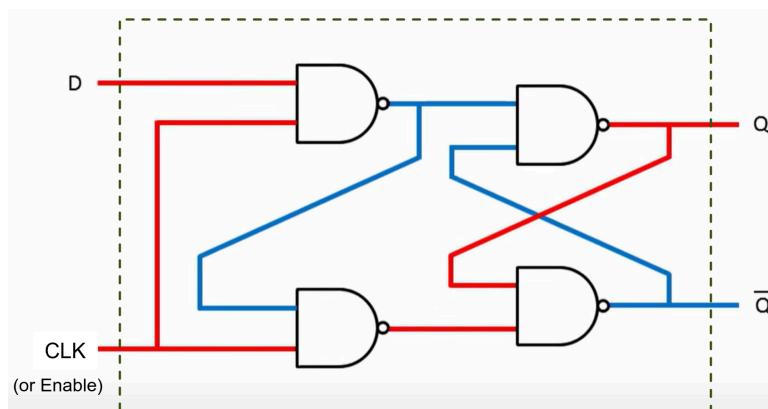

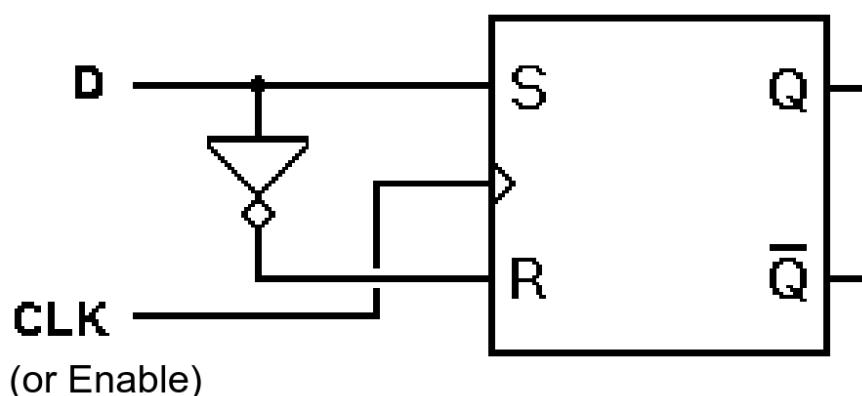

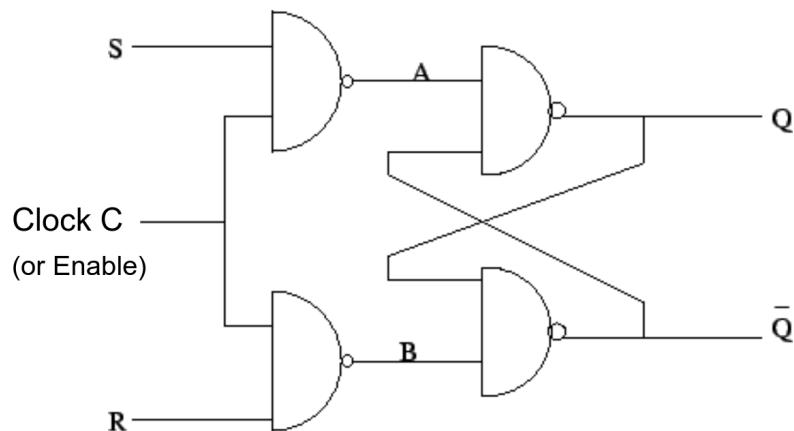

Input 1 (X)	Input 2 (Y)	Output ($\overline{X \oplus Y}$)
0	0	1
0	1	0
1	0	0
1	1	1

6.7.2 Circuit diagrams

6.8 D flip-flop

- The D flip-flop is a device that is able to store a single bit.
- It is usually used in CPU registers.

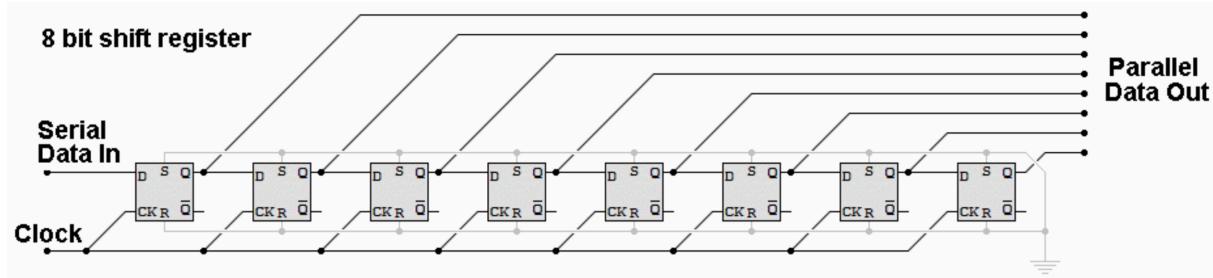

6.8.1 Truth table

S	R	CLK (or Enable)	$Q(t + 1)$	Comments
0	0	X	$Q(t)$	No change
0	1	↑	0	Reset
0	1	↑	1	Set
1	1	↑	?	Invalid

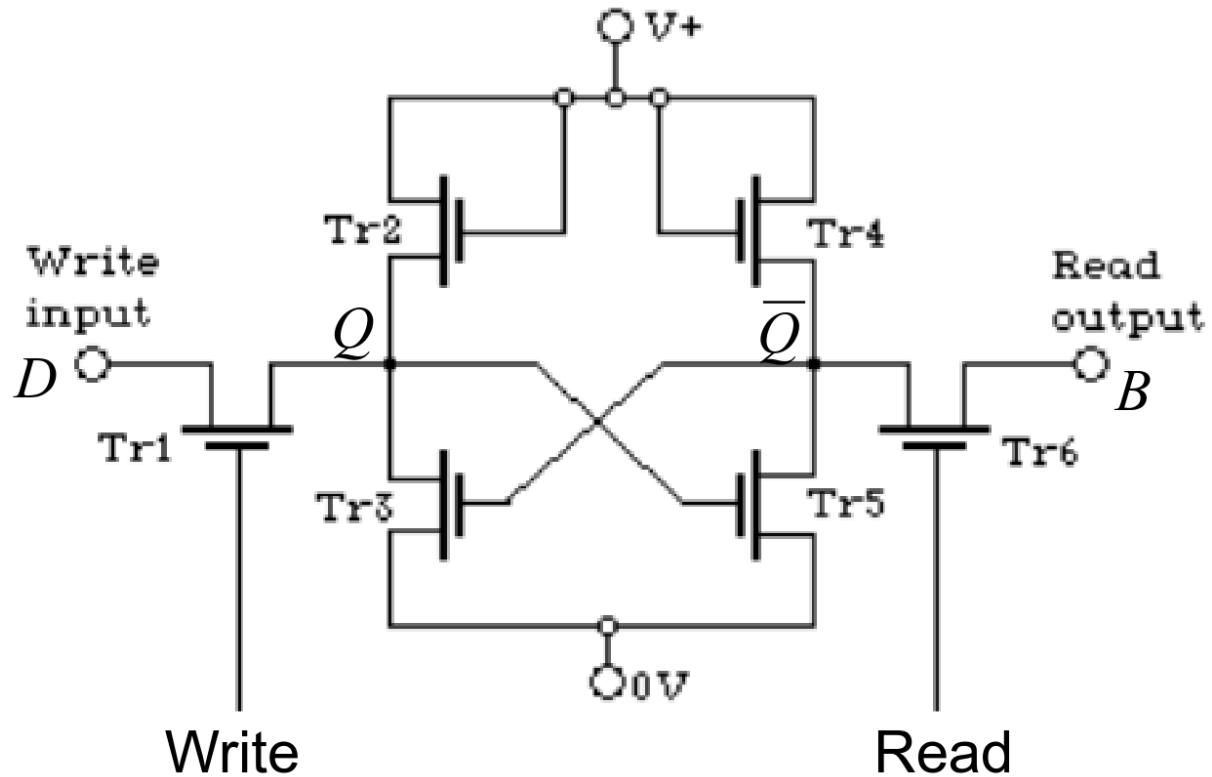

The ↑ shows that the device only responds on the rising edge.

6.9 8-bit shift register

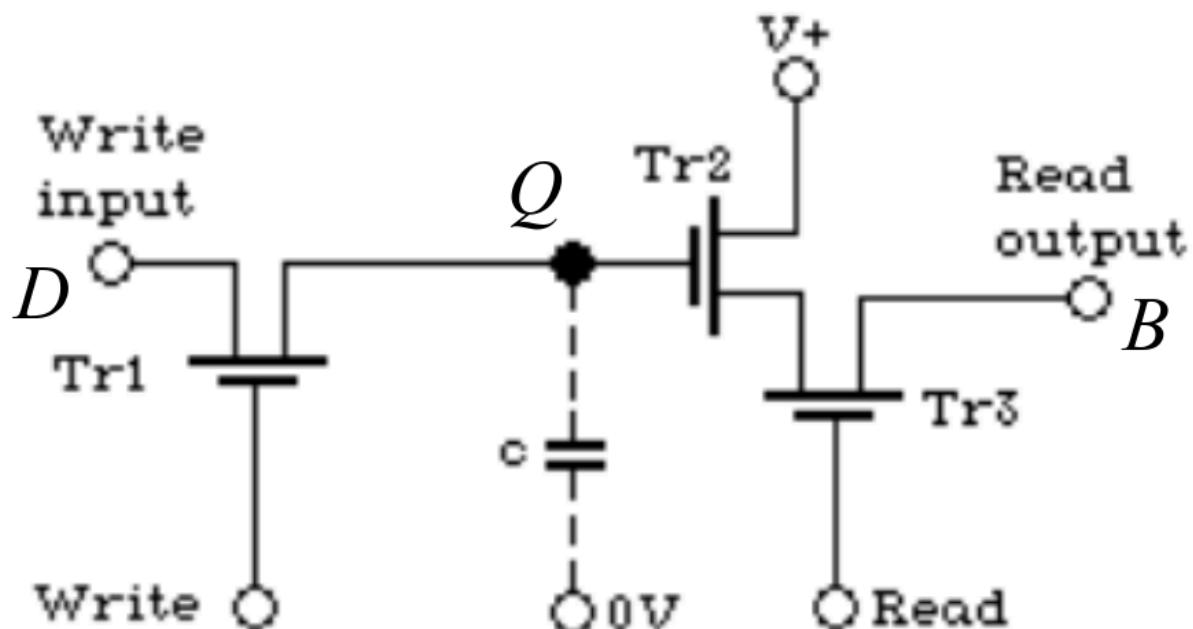

6.10 Single bit Static RAM (SRAM)

- Static RAM can continue to store memory even when the power is switched off, but it is more expensive than dynamic RAM.
- Write operation
 - “Write” line is in logic high.
 - Transistor Tr_1 is on.
 - $Q = D$
- Read operation
 - “Read” line is in logic high.
 - Transistor Tr_5
 - $B = 1 - Q$

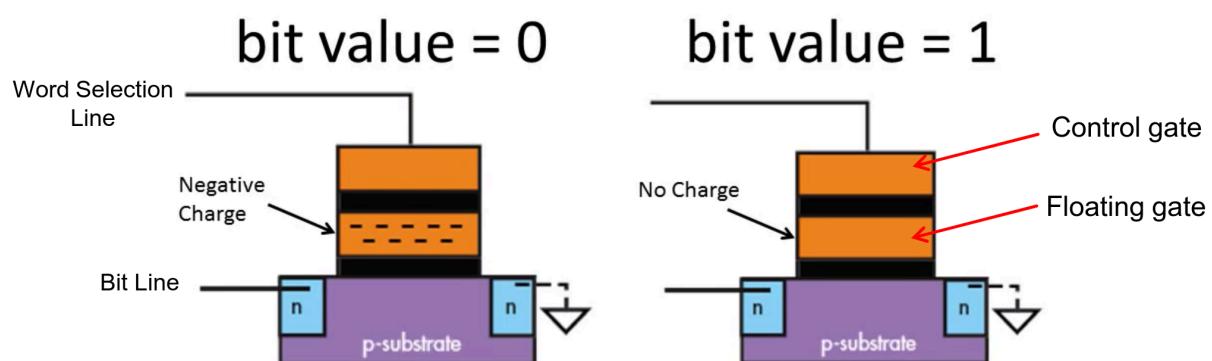

6.11 Single bit Dynamic RAM (DRAM)

- Dynamic RAM cannot store memory after it is powered off due to the capacitor losing its charge.
However, it is cheaper than static RAM due to having fewer transistors.
- Write operation
 - “Write” line is in logic high.
 - Transistor $Tr1$ is on.
 - $Q = D$
- Read operation
 - “Read” line is in logic high.
 - Transistor $Tr3$
 - $B = Q$

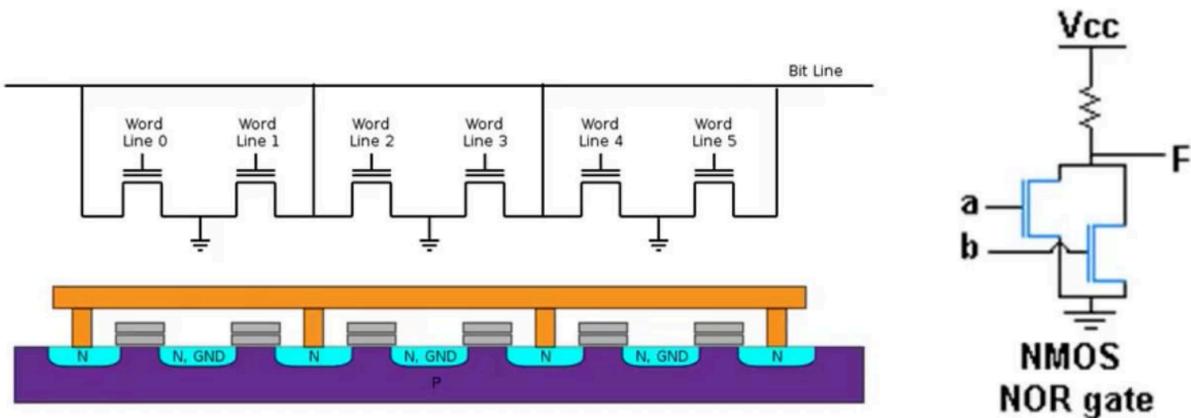

6.12 1-bit flash cell

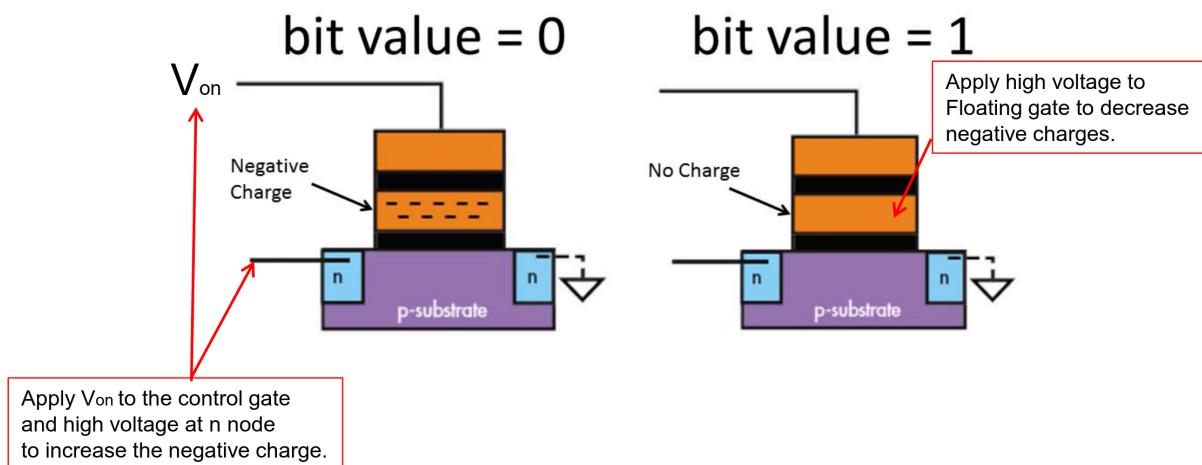

A 1-bit flash cell is made of a single level cell, which has:

- 2 charge states
- 1 bit per floating gate transistor

6.12.1 Line of flash cells

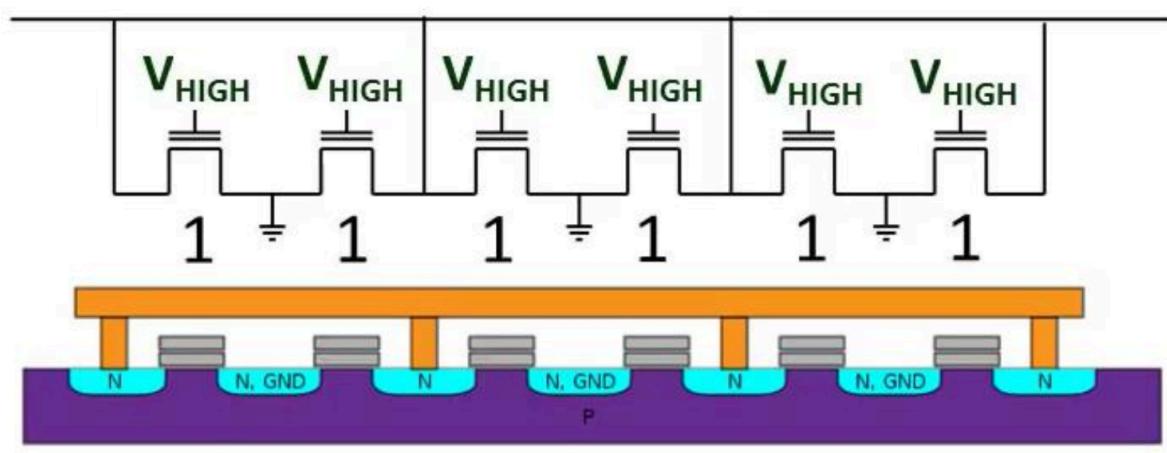

6.12.2 Writing

6.12.3 NOR erasing

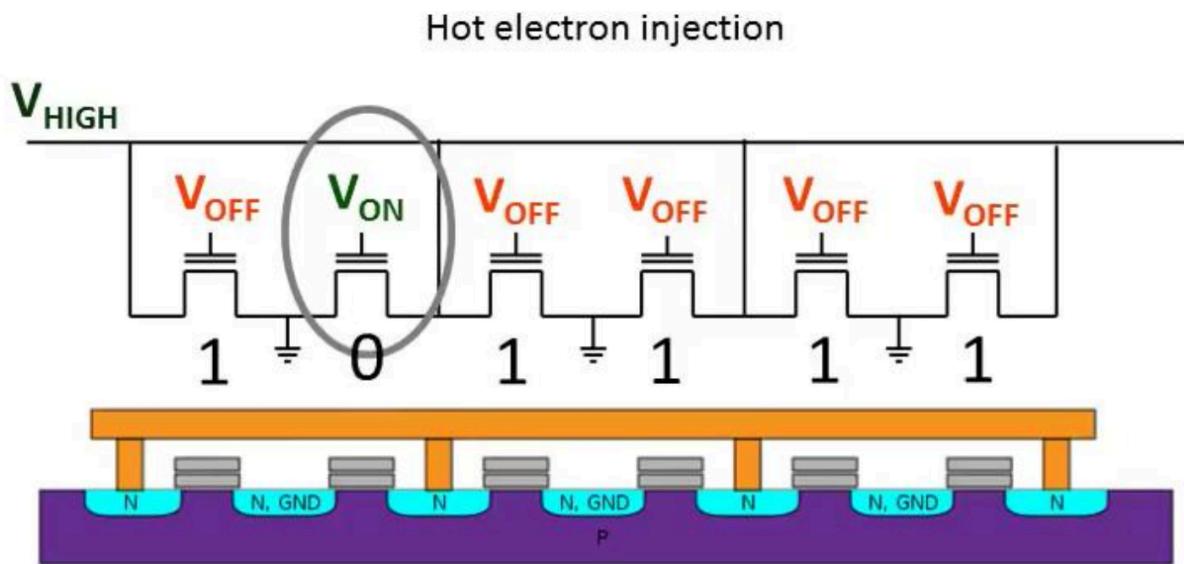

NOR erasing sets all bits to 1.

Block erasure via tunneling

6.12.4 NOR writing

NOR writing sets 0s.

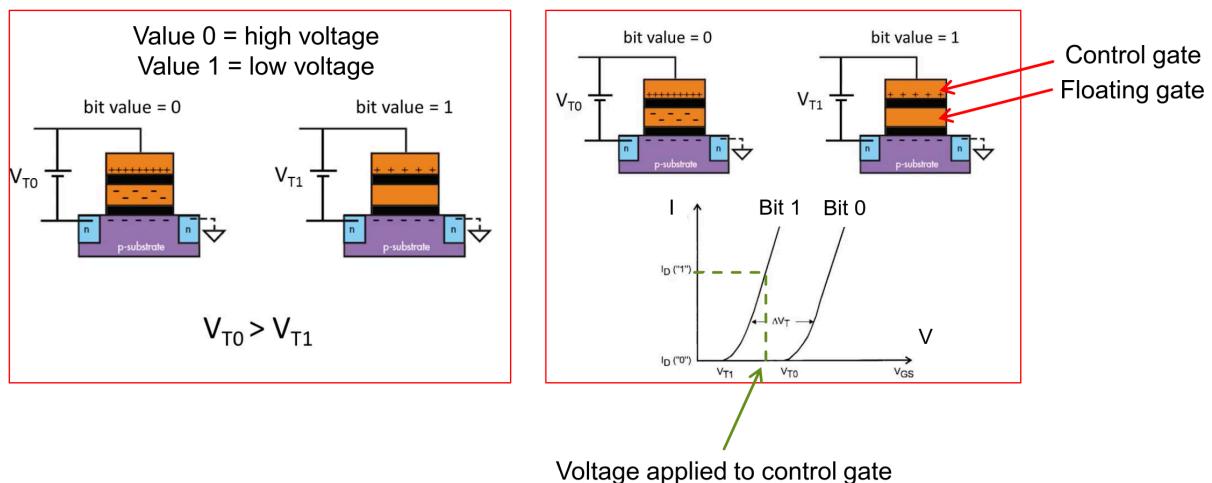

6.12.5 Reading

- To read from a flash cell, a voltage is applied to the control gate.
- The voltage is in between the voltage of the flash cell when the bit value is 0, and the voltage of the flash cell when the bit value is 1, i.e.

$$V_{T1} > V_{GS} > V_{T0}$$

- If there is no current, the output value is 0.
- If there is a current, the output value is 1.

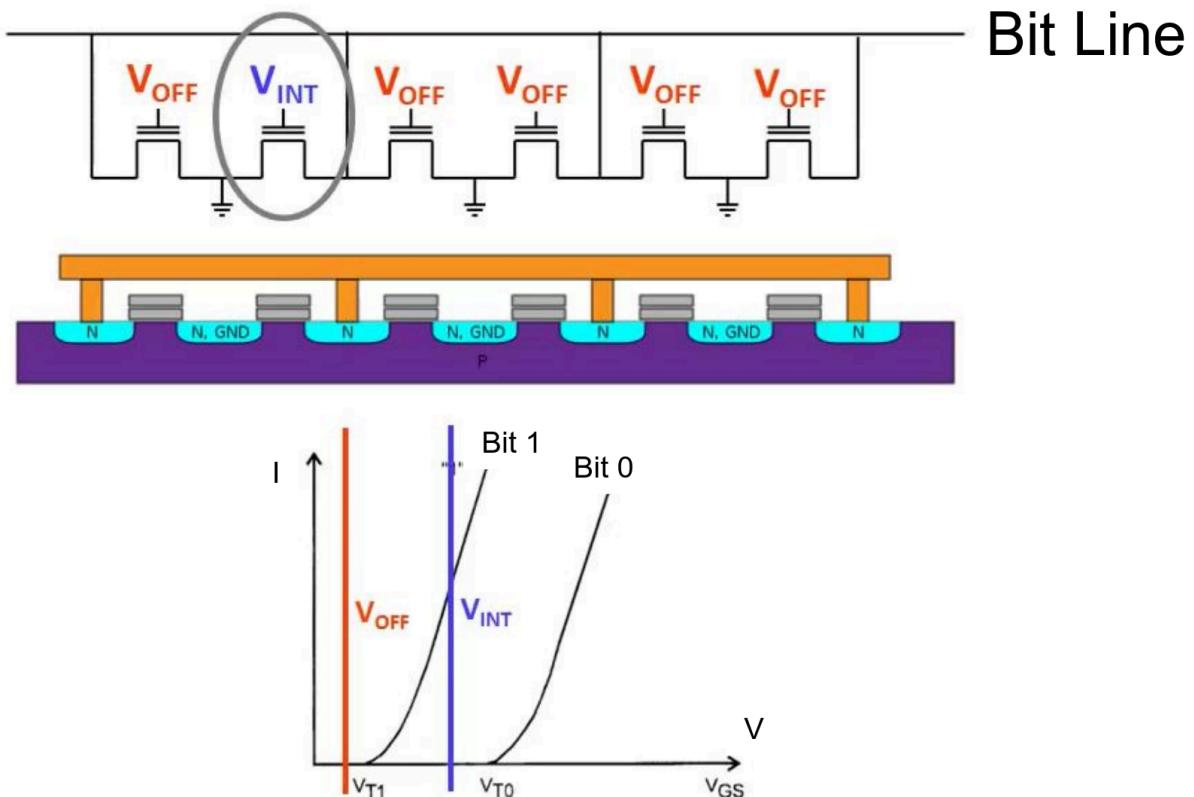

6.12.6 NOR reading

- NOR reading is used to read a single bit from a flash cell line.
- It also uses the same principles as the normal reading, which means the given voltage is in between the voltage of the flash cell when the bit value is 0, and the voltage of the flash cell when the bit value is 1, i.e.

$$V_{T1} > V_{GS} > V_{T0}$$

- Similarly, if there is no current, the output value is 0.
- If there is a current, the output value is 1.

7 Number representation

7.1 History of number systems

- Gottfried Wilhelm Leibniz (1646–1716) is the self-proclaimed inventor of the binary system and is considered as such by most historians of mathematics and mathematicians. However, systems related to binary numbers have appeared earlier in multiple cultures including Ancient Egypt, China, and India.
- Modern methods of writing decimals were invented less than 500 years ago. However, the use of decimals in various forms can be traced back thousands of years. The Babylonians used a number system based on 60 and extend it to deal with numbers less than 1. Some use of decimals was also made in ancient China, medieval Arabia and in Renaissance Europe.
- Swedish American engineer John Williams Nystrom developed the hexadecimal notation system in 1859.
- The eight digits of the octal system are 0, 1, 2, 3, 4, 5, 6, and 7. The octal system was first discovered in 1716 by Emanuel Swedenborg, although linguists speculate that it was discovered by the Proto-Indo-Europeans, a group of Neolithic people ancestors to the Indo-European people of the Bronze Age.

7.2 Binary number system

7.2.1 Format of binary numbers

- A binary number consists of a series of digits.
- A digit has its value and position in the series.
- One digit on the left is 2 times the digit on the right.
- For example, $1_{MSB}1100111000111_{LSB}$
- Hence, we can represent binary numbers in the following way:

$$V = D_{n-1}D_{n-2}\cdots D_1D_0$$

- Where:

$$D_i \in [0, 1], \quad i = 0, 1, 2, \dots \text{ or } i = -1, -2, \dots$$

$$V_n = D_{n-1}2^{n-1} + D_{n-2}2^{n-2} + \cdots + D_12^1D_02^0$$

7.2.2 Integer example

Binary numbers	Corresponding decimal values
00001111	$8 + 4 + 2 + 1 = 15$
11110000	$128 + 64 + 32 + 16 = 240$
11001100	$128 + 64 + 8 + 4 = 204$
00110011	$32 + 16 + 2 + 1 = 51$

7.2.3 Fractional example

Binary numbers	Corresponding decimal values
0.00001111	$0.0313 + 0.0156 + 0.0078 + 0.0039$
0.11110000	$0.5 + 0.25 + 0.125 + 0.0625$
0.11001100	$0.5 + 0.25 + 0.0313 + 0.0156$
0.00110011	$0.125 + 0.0625 + 0.0078 + 0.0039$

7.2.4 Binary addition

- Input:

$$V_1 = A_{n-1}2^{n-1} + A_{n-2}2^{n-2} + \cdots + A_12^1 + A_0 + 2^0$$

$$V_2 = B_{n-1}2^{n-1} + B_{n-2}2^{n-2} + \cdots + B_12^1 + B_0 + 2^0$$

- Output:

$$V_3 = C_{n-1}2^{n-1} + C_{n-2}2^{n-2} + \cdots + C_12^1 + C_0 + 2^0$$

- Rules:

- $0 + 0 = 0$
- $0 + 1 = 1$
- $1 + 0 = 1$
- $1 + 1 = 0$ with a carry of 1

$$\begin{array}{r}
 \text{1} \quad \text{1} \quad \text{1} \quad \text{0} \quad \text{0} \quad \text{0} \quad \text{Carry} \\
 1 \quad 0 \quad 1_2 \quad = \quad 5_{10} \quad \text{Augend} \\
 + \quad \quad \quad 1 \quad 1_2 \quad = \quad 3_{10} \quad \text{Addend} \\
 \hline
 1 \quad 10 \quad 10 \quad 10 \quad = \quad 8_{10}
 \end{array}$$

- Example:

- Augend:

11110000

- Addend:

11001100

- Result:

$$\begin{array}{r}
 \text{1} \quad \text{1} \quad \text{0} \quad \text{Carry} \\
 1 \quad 1 \quad 1 \quad 1 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad \text{Augend} \\
 + \quad 1 \quad 1 \quad 0 \quad 0 \quad 1 \quad 1 \quad 0 \quad 0 \quad \text{Addend} \\
 \hline
 \textcolor{red}{1} \quad 1 \quad 0 \quad 1 \quad 1 \quad 1 \quad 1 \quad 0 \quad 0
 \end{array}$$

7.2.5 Binary subtraction

- Input:

$$V_1 = A_{n-1}2^{n-1} + A_{n-2}2^{n-2} + \dots + A_12^1 + A_0 + 2^0$$

$$V_2 = B_{n-1}2^{n-1} + B_{n-2}2^{n-2} + \dots + B_12^1 + B_0 + 2^0$$

- Output:

$$V_3 = C_{n-1}2^{n-1} + C_{n-2}2^{n-2} + \dots + C_12^1 + C_0 + 2^0$$

- Rules:

- $0 - 0 = 0$
- $0 - 1 = 1$ with a borrow of 1
- $1 - 0 = 1$
- $1 - 1 = 0$

$$\begin{array}{r}
 & 1 & 0 & 0 & 0 & 0 & \text{Borrow} \\
 & 1 & 1 & 0 & 1 & _2 & = & 5_{10} & \text{Minuend} \\
 - & & 1 & 1 & 1 & _2 & = & 3_{10} & \text{Subtrahend} \\
 \hline
 & 0 & 1 & 0 & 0 & _2 & = & 2_{10}
 \end{array}$$

- Example:

- Minuend:

11110000

- Subtrahend:

11001100

- Result:

$$\begin{array}{r}
 & 0 & 0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & \text{Borrow} \\
 & 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & \text{Minuend} \\
 - & & 1 & 1 & 0 & 0 & 1 & 1 & 0 & 0 & \text{Subtrahend} \\
 \hline
 & \textcolor{red}{0} & 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0
 \end{array}$$

7.3 Decimal number system

- A decimal number consists of a series of digits.
- A digit has its value and its position in the series.
- One digit on the left is 10 times the digit on the right.
- For example, 1234000.
- Hence, we can represent decimal numbers in the following way:

$$V = D_{n-1}D_{n-2}\cdots D_1D_0$$

- Where:

$$D_i \in [0, 1, 2, 3, 4, 5, 6, 7, 8, 9], \quad i = 0, 1, 2, \dots \text{ or } i = -1, -2, \dots$$

$$V_n = D_{n-1}10^{n-1} + D_{n-2}10^{n-2} + \cdots + D_110^1D_010^0$$

7.3.1 Integer example

Decimal numbers	Corresponding decimal values
00002234	$2000 + 200 + 30 + 4$
67890000	$60000000 + 7000000 + 800000 + 90000$
34008900	$30000000 + 400000 + 8000 + 900$
00890034	$800000 + 90000 + 30 + 4$

7.3.2 Fractional example

Decimal numbers	Corresponding decimal values
0.00002234	$0.00002 + 0.000002 + 0.000003 + 0.00000004$
0.67890000	$0.6 + 0.07 + 0.008 + 0.0009$
0.34008900	$0.3 + 0.04 + 0.00008 + 0.000009$
0.00890034	$0.008 + 0.009 + 0.0000003 + 0.00000004$

7.3.3 Decimal addition

- Input:

$$V_1 = A_{n-1}10^{n-1} + A_{n-2}10^{n-2} + \cdots + A_110^1 + A_0 + 10^0$$

$$V_2 = B_{n-1}10^{n-1} + B_{n-2}10^{n-2} + \cdots + B_110^1 + B_0 + 10^0$$

- Output:

$$V_3 = C_{n-1}10^{n-1} + C_{n-2}10^{n-2} + \cdots + C_110^1 + C_0 + 10^0$$

- Rules:

- If $A_i + B_i > 9$, $C_i = A_i + B_i - 10$, with a carry of 1.
- Otherwise, $C_i = A_i + B_i$.

$$\begin{array}{r} 1 \ 1 \ 0 \quad \text{Carry} \\ 9 \ 5 \quad \text{Augend} \\ + \quad 1 \ 6 \quad \text{Addend} \\ \hline 1 \ 1 \ 1 \end{array}$$

- Example:

- Augend:

67890000

- Addend:

34008900

- Result:

$$\begin{array}{r} 1 \ 1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \quad \text{Carry} \\ 6 \ 7 \ 8 \ 9 \ 0 \ 0 \ 0 \ 0 \quad \text{Augend} \\ + \quad 3 \ 4 \ 0 \ 0 \ 8 \ 9 \ 0 \ 0 \quad \text{Addend} \\ \hline 1 \ 0 \ 1 \ 8 \ 9 \ 8 \ 9 \ 0 \ 0 \end{array}$$

7.3.4 Decimal subtraction

- Input:

$$V_1 = A_{n-1}10^{n-1} + A_{n-2}10^{n-2} + \dots + A_110^1 + A_0 + 10^0$$

$$V_2 = B_{n-1}10^{n-1} + B_{n-2}10^{n-2} + \dots + B_110^1 + B_0 + 10^0$$

- Output:

$$V_3 = C_{n-1}10^{n-1} + C_{n-2}10^{n-2} + \dots + C_110^1 + C_0 + 10^0$$

- Rules:

- If $A_i < B_i$, $C_i = 10 + A_i - B_i - 10$, with a borrow of 1.
- Otherwise, $C_i = A_i - B_i$.

$$\begin{array}{r}
 \textcolor{blue}{1} \quad \textcolor{blue}{0} \quad \text{Borrow} \\
 9 \quad \overset{1}{5}_{10} \quad \text{Minuend} \\
 - \quad 1 \quad 6_{10} \quad \text{Subtrahend} \\
 \hline
 7 \quad 9_{10}
 \end{array}$$

- Example:

- Minuend:

67890000

- Subtrahend:

34008900

- Result:

$$\begin{array}{r}
 0 \quad 0 \quad 0 \quad 0 \quad 1 \quad 1 \quad 0 \quad 0 \quad 0 \quad \text{Borrow} \\
 6 \quad 7 \quad 8 \quad 9 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad \text{Minuend} \\
 - \quad 3 \quad 4 \quad 0 \quad 0 \quad 8 \quad 9 \quad 0 \quad 0 \quad 0 \quad \text{Subtrahend} \\
 \hline
 0 \quad 0 \quad 3 \quad 3 \quad 8 \quad 8 \quad 1 \quad 1 \quad 0 \quad 0
 \end{array}$$

7.3.5 Hexadecimal number system

- A hexadecimal number consists of a series of digits.
- A digit has its value and its position in the series.
- One digit on the left is 16 times the digit on the right.
- For example, ABCD5678.
- Hence, we can represent hexadecimal numbers in the following way:

$$V = D_{n-1}D_{n-2}\cdots D_1D_0$$

- Where:

$$D_i \in [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, A, B, C, D, E, F], \quad i = 0, 1, 2, \dots \text{ or } i = -1, -2, \dots$$

$$V = D_{n-1}16^{n-1} + D_{n-2}16^{n-2} + \cdots + D_116^1 + D_016^0$$

7.3.6 Integer example

Hexadecimal numbers	Corresponding decimal values
00005688	$20480 + 1536 + 128 + 8$
ABCD0000	$2684400000 + 184549376 + 12582912 + 851968$
CD007800	$3221200000 + 218103808 + 28672 + 2048$
007800CD	$7340032 + 524288 + 192 + 13$

7.3.7 Fractional example

Hexadecimal numbers	Corresponding decimal values
0.00005688	$0.0000047684 + 0.00000035763 + 0.000000029802 + 0.0000000018626$
0.ABCD0000	$0.625 + 0.043 + 0.0029 + 0.00019836$
0.CD007800	$0.75 + 0.0508 + 0.0000066757 + 0.00000047684$
0.007800CD	$0.0017 + 0.00012207 + 0.000000044703 + 0.0000000030268$

7.3.8 Hexadecimal addition

- Input:

$$V_1 = A_{n-1}16^{n-1} + A_{n-2}16^{n-2} + \dots + A_116^1 + A_0 + 16^0$$

$$V_2 = B_{n-1}16^{n-1} + B_{n-2}16^{n-2} + \dots + B_116^1 + B_0 + 16^0$$

- Output:

$$V_3 = C_{n-1}16^{n-1} + C_{n-2}16^{n-2} + \dots + C_116^1 + C_0 + 16^0$$

- Rules:

- If $A_i + B_i > F$, $C_i = A_i + B_i - 16$, with a carry of 1
- Otherwise, $C_i = A_i + B_i$

$$\begin{array}{r}
 \begin{array}{ccccc} 1 & 0 & 1 & 1 & 0 \end{array} & \text{Carry} \\
 \begin{array}{ccccc} F & 0 & B & A & \end{array} & \text{Augend} \\
 + & \begin{array}{ccccc} E & 9 & A & D & \end{array} & \text{Addend} \\
 \hline
 \begin{array}{ccccc} 1 & D & A & 6 & 7 \end{array} & \text{Sum}
 \end{array}$$

- Example:

- Augend:

ABCD0000

- Addend:

007800CD

- Result:

$$\begin{array}{r}
 \begin{array}{cccccccccc} 0 & 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & \text{Carry} \end{array} \\
 \begin{array}{cccccccccc} A & B & C & D & 0 & 0 & 0 & 0 & 0 & \text{Augend} \end{array} \\
 + & \begin{array}{cccccccccc} 0 & 0 & 7 & 8 & 0 & 0 & C & D & \text{Addend} \end{array} \\
 \hline
 \begin{array}{cccccccccc} 0 & A & C & 4 & 5 & 0 & 0 & C & D \end{array}
 \end{array}$$

7.3.9 Hexadecimal subtraction

- Input:

$$V_1 = A_{n-1}16^{n-1} + A_{n-2}16^{n-2} + \dots + A_116^1 + A_0 + 16^0$$

$$V_2 = B_{n-1}16^{n-1} + B_{n-2}16^{n-2} + \dots + B_116^1 + B_0 + 16^0$$

- Output:

$$V_3 = C_{n-1}16^{n-1} + C_{n-2}16^{n-2} + \dots + C_116^1 + C_0 + 16^0$$

- Rules:

- If $A_i < B_i$, $C_i = 16 + A_i - B_i$, with a borrow of 1
- Otherwise, $C_i = A_i - B_i$

0	0	1	1	1	Borrow
D	E	A	9	Minuend	
-	4	F	B	D	Subtrahend
					<hr/>
0	8	E	E	C	

- Example:

- Minuend:

67890000

- Subtrahend:

34008900

- Result:

0	0	0	0	1	1	0	0	0	Borrow
6	7	8	9	0	0	0	0	0	Minuend
-	3	4	0	0	8	9	0	0	Subtrahend
									<hr/>
0	3	3	8	8	7	7	0	0	

7.3.10 Hexadecimal ASCII table

For example, 0x42 refers to the character “B”.

LEAST SIGNIFICANT BITS	Hexadecimal Codes		MOST SIGNIFICANT BITS					
	0	1	2	3	4	5	6	7
0	Null	Data Link Escape	Space	0	@	P	‘	p
1	Start of Heading	Device Control 1	!	1	A	Q	a	q
2	Start of Text	Device Control 2	“	2	B	R	b	r
3	End of Text	Device Control 3	#	3	C	S	c	s
4	End of Transmit	Device Control 4	\$	4	D	T	d	t
5	Enquiry	Neg Acknowledge	%	5	E	U	e	u
6	Acknowledge	Synchronous Idle	&	6	F	V	f	v
7	Bell	End of Trans Block	,	7	G	W	g	w
8	Backspace	Cancel	(8	H	X	h	x
9	Horizontal Tab	End of Medium)	9	I	Y	i	y
A	Line Feed	Substitute	*	:	J	Z	j	z
B	Vertical Tab	Escape	+	;	K	[k	{
C	Form Feed	File Separator	,	<	L	\	l	
D	Carriage Return	Group Separator	-	=	M]	m	}
E	Shift Out	Record Separator	.	>	N	^	n	~
F	Shift In	Unit Separator	/	?	O	_	o	Delete

7.4 Conversion look-up table

Hex	Binary	Decimal
0	0000	0
1	0001	1
2	0010	2
3	0011	3
4	0100	4
5	0101	5
6	0110	6
7	0111	7
8	1000	8
9	1001	9
A	1001	10
B	1011	11
C	1100	12
D	1101	13
E	1110	14
F	1111	15

7.4.1 Conversion from binary to hexadecimal

- Rules:
 - 1 digit of hexadecimal corresponds to 4 digits of binary.
 - Group every 4 digits of binary together and replace it with the corresponding digit of hexadecimal.
- Example:
 - Binary input:

$\overbrace{1111}^F \overbrace{1110}^E \overbrace{1100}^C \overbrace{1000}^8$

- Hexadecimal output:
 - $F = 1111$
 - $E = 1110$
 - $C = 1100$
 - $8 = 1000$
 - Hexadecimal = 0xFEC8

7.4.2 Conversion from hexadecimal to binary

- Rules:
 - 1 digit of hexadecimal corresponds to 4 digits of binary.
 - Expand every digit of hexadecimal into a series of 4 digits of binary and replace it with corresponding 4 digits of binary.
- Example:
 - Hexadecimal input:

0x \overbrace{F}^{1111} \overbrace{E}^{1110} $\overbrace{8}^{1000}$ $\overbrace{9}^{1001}$ \overbrace{A}^{1010} \overbrace{B}^{1011} $\overbrace{5}^{0101}$ $\overbrace{6}^{0110}$

- Binary output:
 - $F = 1111$ $E = 1110$ $8 = 1000$ $9 = 1001$
 - $A = 1010$ $B = 1011$ $5 = 0101$ $6 = 0110$
 - Binary = 1111 1110 1000 1001 1010 1011 0101 0110

7.4.3 Conversion from decimal to binary, integer part

- Decimal input:

$$V_{\text{decimal}} = D_{n-1}10^{n-1} + D_{n-2}10^{n-2} + \dots + D_110^1 + D_010^0$$

- Binary output:

$$V_{\text{binary}} = B_{n-1}2^{n-1} + B_{n-2}2^{n-2} + \dots + B_12^1 + B_02^0$$

- Process:

- Divide the input by 2. The remainder is the first digit of the binary output.
- Divide the quotient by 2. The remainder is the second digit of the binary output.
- Continue the process until the **quotient becomes zero**.

- Example:

- Input: 57 in decimal
 - 1. $\frac{57}{2} = 28$, Remainder = 1 (Binary number will end with 1)
 - 2. $\frac{28}{2} = 14$, Remainder = 0
 - 3. $\frac{14}{2} = 7$, Remainder = 0
 - 4. $\frac{7}{2} = 3$, Remainder = 1
 - 5. $\frac{3}{2} = 1$, Remainder = 1
 - 6. $\frac{1}{2} = 0$, Remainder = 1 (Binary number will start with 1)
- Output: 111001 in binary

7.4.4 Conversion from decimal to binary, fractional part

- Process:

- Multiply the input by 2. The decimal number before the decimal point is the first digit of the binary output after the decimal point.
- Multiply the fractional part from the previous result by 2. The decimal number before the decimal point is the second digit of the binary output after the decimal point.
- Continue the process until the quotient becomes **zero** or a **periodic number**, which means the number in binary keeps repeating.
- Read the number starting from the **top**, the first result is the first digit after the decimal point.

- Example:

- Input: 0.375 in decimal
 - 1. $0.375 \times 2 = 0.75$, Fractional part = 0.75 with carry = 0
 - 2. $0.75 \times 2 = 1.50$, Fractional part = 0.50 with carry = 1
 - 3. $0.50 \times 2 = 1.00$, Fractional part = 0.00 with carry = 1
- Output: 0.011 in binary

- Faster method:

- Multiply the fractional part by 2 to the power of the number of decimal places required, i.e.

$$\text{Fractional part} \times 2^n$$

Where n is the number of decimal places required.

- Round the result to the nearest whole number and convert the result to binary.

- Example:

- Input: 0.375 in decimal, which has 3 decimal places, so $n = 3$:
 - 1. $0.375 \times 2^3 = 3$
 - 2. $3_{10} = 011_2$
- Output: 0.011 in binary

7.4.5 Example of converting a decimal number with decimals to binary

Input: 43.167 in decimal.

- For the integer part:
 1. $\frac{43}{2} = 21$, Remainder = 1
 2. $\frac{21}{2} = 10$, Remainder = 1
 3. $\frac{10}{2} = 5$, Remainder = 0
 4. $\frac{5}{2} = 2$, Remainder = 1
 5. $\frac{2}{2} = 1$, Remainder = 0
 6. $\frac{1}{2} = 0$, Remainder = 1
- For the fractional part:
 1. $0.167 \times 2 = 0.334$
 2. $0.334 \times 2 = 0.668$
 3. $0.668 \times 2 = 1.336$
 4. $0.336 \times 2 = 0.672$
 5. $0.672 \times 2 = 1.344$

Output: 101011.00101 in binary.

7.4.6 Conversion from decimal to hexadecimal, integer part

- Decimal input:

$$V_{\text{decimal}} = D_{n-1}10^{n-1} + D_{n-2}10^{n-2} + \dots + D_110^1 + D_010^0$$

- Hexadecimal output:

$$V_{\text{hexadecimal}} = H_{n-1}16^{n-1} + H_{n-2}16^{n-2} + \dots + H_116^1 + H_016^0$$

- Process:
 - Divide the input by 16. The remainder is the first digit of the hex output.
 - Divide the quotient by 16. The remainder is the second digit of the hex output.
 - Continue the process until the quotient becomes zero.
- Example:
 - Input: 35243 in decimal
 1. $\frac{35243}{16} = 2202$, Remainder = 11 → B (hex number will end with B)
 2. $\frac{2202}{16} = 137$, Remainder = 10 → A
 3. $\frac{137}{16} = 8$, Remainder = 9
 4. $\frac{8}{16} = 0$, Remainder = 8 (hex number will start with 8)

Therefore, collecting the remainders, $35243_{10} = 89AB_{16}$. To check:

$$(8 \times 16^3) + (9 \times 16^2) + (10 \times 16^1) + (11 \times 16^0) = 35243_{10}$$

- Output: 89AB in hexadecimal

7.4.7 Conversion from decimal to hexadecimal, fractional part

- Process:
 - Multiply the input by 16. The decimal number before the decimal point is the first digit of the binary output after the decimal point.
 - Multiply the fractional part from the previous result by 16. The decimal number before the decimal point is the second digit of the binary output after the decimal point.
 - Continue the process until the quotient becomes zero or a periodic number
 - Read the number starting from the top, the first result is the first digit after the decimal point.
- Example 1:
 - Input: 0.375 in decimal
 - 1. $0.375 \times 16 = 6.0$
 - Output: 0.6 in hexadecimal
- Example 2:
 - Input: 0.987 in decimal
 - 1. $0.987 \times 16 = 15.792 \rightarrow F$
 - 2. $0.792 \times 16 = 12.672 \rightarrow C$
 - 3. $0.672 \times 16 = 10.752 \rightarrow A$
 - 4. $0.752 \times 16 = 12.032 \rightarrow C$
 - Output: 0.FCAC in hexadecimal

7.5 Representation of integers

7.5.1 Binary-coded decimal of integers

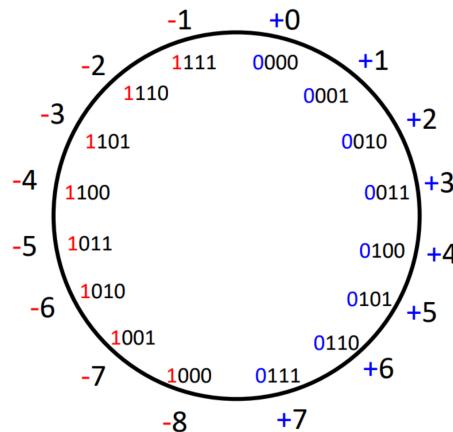

- Rules:
 - Each digit of decimal is represented by four digits of binary.
 - 0 = 0000, 1 = 0001, 2 = 0010, 3 = 0011, 4 = 0100
 - 5 = 0101, 6 = 0110, 7 = 0111, 8 = 1000, 9 = 1001
- Examples:
 - Decimal(9879) = Binary(1001 1000 0111 1001)
 - Decimal(12345) = Binary(0001 0010 0011 0100 0101)

7.5.2 Signed magnitude format of integers

- Rules:
 - Allocate the most-significant bit (MSB) to represent the signs.
 - Allocate the remaining bits to represent the values.
- Examples:
 - Binary with 4 bits:
 - Max = 0 111 → 7
 - Min = 1 111 → -7
 - Binary with 8 bits:
 - Max = 0 111 1111 → 127
 - Min = 1 111 1111 → -127
 - Binary with 16 bits:
 - Max = 0 111 1111 1111 1111 → 32767
 - Min = 1 111 1111 1111 1111 → -32767
 - Binary with 32 bits:
 - Max = 0 111 1111 1111 1111 1111 1111 1111 → 2,147,483,647
 - Min = 1 111 1111 1111 1111 1111 1111 1111 → -2,147,483,647

7.5.3 Two's complement format of integers

- Rules:
 - For a binary number of N bits, the positive numbers are represented by the bits from 0 (LSB) to $N - 2$ and bit $N - 1$ (MSB) is zero.
 - For a binary number of N bits, the negative numbers are represented by the two's complements of their positive numbers.
 - A two's complement is equal to bit-wise complement plus 1.
- Examples:
 - 4 bit binary of integer 6 = 0110
 - 4 bit binary of integer $-6 = 1001 + 1 = 1010$
 - 8 bit binary of integer 102 = 0110 0110
 - 8 bit binary of integer $-102 = 1001\ 1001 + 1 = 1001\ 1010$
- Diagram:

- 8 positive numbers
- 8 negative numbers
- $+8 = 1000$
- $-8 = 0111 + 1 = 1000$
- $+8 = -8$
- So, we ignore +8

7.5.4 Reasons to use two's complement format

Addition:

- Addition not dependent on the signs of operand.
- No need to compare magnitudes to determine sign of result.

Subtraction:

- Subtraction is treated as an addition.
- Add the negative of the subtrahend to the minuend.

Simple implementation:

- Adder unit.
- Negation circuit unit.

The simpler addition and subtraction scheme makes two's complement the most common choice for integer number systems within digital systems.

7.6 Representation of floating point numbers

7.6.1 Binary-coded decimal of floating-point numbers

- Rules:
 - Each digit of decimal is represented by 4 digits of binary.
 - 0 = 0000, 1 = 0001, 2 = 0010, 3 = 0011, 4 = 0100
 - 5 = 0101, 6 = 0110, 7 = 0111, 8 = 1000, 9 = 1001
- Examples:
 - Decimal(9879.34) = Binary(1001 1000 0111 1001).Binary(0011 0100)
 - Decimal(12345.5) = Binary(0001 0010 0011 0100 0101).Binary(0101)

7.6.2 Exponent-mantissa format of floating point numbers

Using the 32-bit ANSI/IEEE 754 standard format.

Sign bit (S)	Exponent (E)	Mantissa (M) or Fraction
(1 bit)	(8 bits)	(23 bits)

- Sign bit (S)
 - 0 denotes positive number, 1 denotes negative number.
- Exponent (E)
 - Represents both positive and negative exponents.
 - A bias value of 127_{10} must be added to all exponents, regardless of sign.
- Mantissa or Fraction (M)
 - Represents the leading significant bits in the number.
 - It is stored in the normalised form.

7.6.3 Conversion of decimals to exponent-mantissa format

- Procedure:
 - Convert decimals to binary format.
 - Normalise binary format.
 - Determine exponent.
 - Determine mantissa.
- Example of 2.75 in decimal:
 1. $2.75_{10} = 10.11_2$
 2. In normalised form: $1.011_2 \times 2^1$
 3. Express in 23-bit mantissa without leading 1_2 :

$$M = 011\ 0000\ 0000\ 0000\ 0000\ 0000$$

4. Express 8-bit exponent (E) with added bias:

$$E = 1_{10} + 127_{10} = 128_{10} = 1000\ 0000_2$$

5. Express sign bit (S):

$$S = 0 \quad (\text{positive number})$$

- Example of -0.0625 in decimal:
 1. $-0.0625_{10} = -0.0001_2$
 2. In normalised form: $1.0_2 \times 2^{-4}$
 3. Express in 23-bit mantissa without leading 1_2 :

$$M = 000\ 0000\ 0000\ 0000\ 0000\ 0000$$

4. Express 8-bit exponent (E) with added bias:

$$E = -4_{10} + 127_{10} = 123_{10} = 0111\ 1011_2$$

5. Express sign bit (S):

$$S = 1 \quad (\text{negative number})$$

- Example of -417680 in decimal:
 1. $-417680_{10} = -110\ 0101\ 1111\ 1001\ 0000_2$
 2. In normalised form: $1.10010111110010000_2 \times 2^{18}$
 3. Express in 23-bit mantissa without leading 1_2 :

$$M = 100\ 1011\ 1111\ 0010\ 0000\ 0000$$

4. Express 8-bit exponent (E) with added bias:

$$E = 18_{10} + 127_{10} = 145_{10} = 1010\ 0001_2$$

5. Express sign bit (S):

$$S = 1 \quad (\text{negative number})$$

7.6.4 Zero and infinity in exponent-mantissa format

- Representing $+/-0.0$ in 32-bit ANSI/IEEE 754 standard format

Sign bit (S)	Exponent (E)	Mantissa (M) or Fraction
0/1	0000 0000	000 0000 0000 0000 0000

- Representing $+/-\infty$ in 32-bit ANSI/IEEE 754 standard format

Sign bit (S)	Exponent (E)	Mantissa (M) or Fraction
0/1	1111 1111	000 0000 0000 0000 0000

8 Nature of programming

8.1 Programming versus writing

Programming (using Arm Keil):

- You have a solution in mind.
- You organise your solution.
- You compose your program.
- You test your program.
- You deploy your program.

Writing (using LaTeX or Microsoft Word):

- You have a story in mind.
- You organise your story.
- You compose your texts.
- You proof-read your texts.
- You publish your texts.

8.2 How to organise your solution?

1. Plan arithmetic or logical computations underlying your solution.
2. Allocate memory resources which are indispensable for the implementation of the planned computations.

8.2.1 Example of $(x = (a + b) - c)$

Allocation of memory for the program:

```
EXPORT Start
AREA progA, CODE, READONLY

var_a DCD 5 ; a = 5
var_b DCD 6 ; b = 6
var_c DCD 7 ; c = 7
var_x DCD 0 ; Initialise x to 0
```

Planning of actual computation:

```
Start ADR R4, var_a ; Get the memory address of var_a
      LDR R0, [R4] ; Get the value of var_a
      ADR R4, var_b ; Get the memory address of var_b, reusing R4
      LDR R1, [R4] ; Get the value of var_b
      ADD R3, R0, R1 ; Compute var_a + var_b
      ADR R4, var_c ; Get the memory address of var_c
      LDR R2, [R4] ; Get the value of var_c
      SUB R3, R3, R2 ; Complete the computation of x = (a + b) - c
      ADR R4, var_x ; Get the memory address of var_x
      STR R3, [R4] ; Store the value of x
stop  B stop
      END
```

8.3 Procedure of planning computations

1. Describe your solution in the form of mathematics or logic.
2. Transform your solution into algorithms which consist of a series of arithmetic and logical computations.
3. Draw flowcharts which connect arithmetic and logical computations in terms of their inputs and outputs.
4. Describe flow charts with the use of a programming language.

8.3.1 Example of transforming a solution into an algorithm

Solution:

$$ax^2 + bx + c = 0$$

$$x = \frac{-b + \sqrt{b^2 - 4ac}}{2a}$$

$$x = \frac{-b - \sqrt{b^2 - 4ac}}{2a}$$

Algorithm:

1. First do:

$$y = b^2 - 4ac$$

2. Then do:

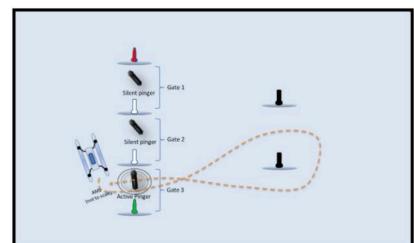

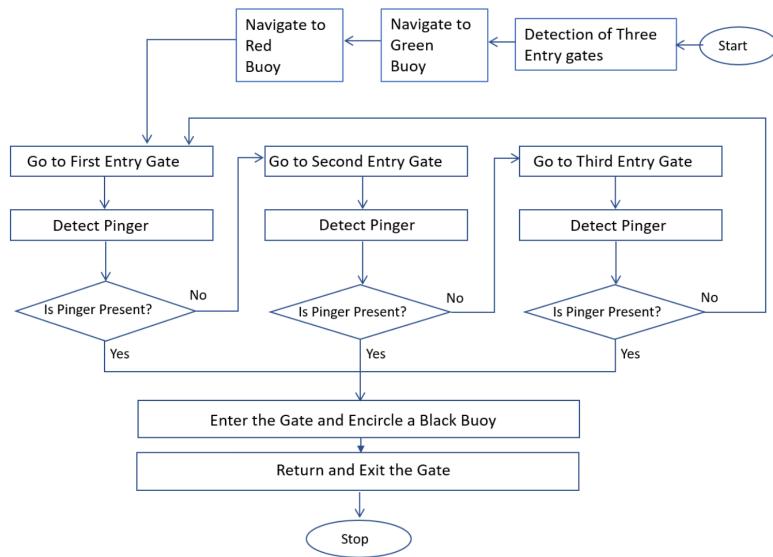

$$z = \sqrt{y}$$

3. Then do:

$$x_1 = \frac{-b + z}{2a}$$

$$x_2 = \frac{-b - z}{2a}$$

8.3.2 Example of flowchart corresponding to algorithm

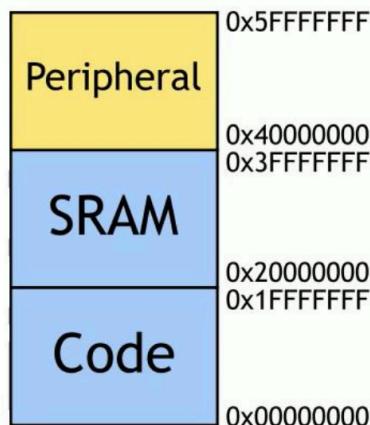

9 Allocation of memory

9.1 Why allocate memory?

- Hardware can support multiple applications running concurrently.
- The ALU is being shared among these applications, which means the application has full access to the ALU during the time when the ALU is allocated to it.
- However, memory units are generally not shared.
- Hence, each application must take care of memory allocation explicitly.

9.2 Memory allocation scenarios

1. Allocation of memory for housing a program itself.
2. Allocation of memory for housing constants, parameters and variables of a program.

- The allocation of memory for the program itself is stored in the code section of ARM memory.
- The allocation of memory for the variables and constants used by a program is stored in the static RAM or SRAM.
- On-chip code, data, and I/O are located in the first 1.5 GiB of memory space.
- Each is allocated 0.5 GiB.
- May use physically separate buses for each space.

9.3 Memory allocation example

```
EXPORT      Start
AREA       progB, CODE, READONLY
var_a     DCD 1      ; a = 1
var_b     DCD 15     ; b = 15
var_z     DCD 0      ; Initialise z to 0

Start          ; z = (a << 2) | (b & 15)

ADR R4, var_a    ; Get the memory address of var_a
LDR R0, [R4]      ; Get the value of var_a
MOV R0, R0, LSL #2 ; Bitwise shift var_a left by 2: R0 = a << 2
ADR R4, var_b    ; Get the memory address of var_b
LDR R1, [R4]      ; Get the value of var_b

; Perform bitwise AND on var_b and 152: r_1 = (b & 152)
AND R1, R1, #15

; Perform bitwise OR on R0 and R1: R1 = (a << 2) | (b & 152)
ORR R1, R0, R1
ADR R4, var_z    ; Get the memory address of var_z

; Store the value of R1 in the memory address of var_z
STR R1, var_z

stop    B  stop
END
```

10 ARM programming tools

10.1 Overview

- The compiler converts from C files (.c) to assembler files (.s).
- The assembler converts from assembler files (.s) to object files (.o).
- The linker converts from object files (.o) to executable files (.exe).
- The linker can link object files (.o) with archive files (.a)

10.2 Assembler directives for memory destination (GCC and ArmClang)

Mnemonic and syntax	Description
.bss <i>symbol</i> , <i>size in bytes</i> [, <i>alignment</i> [, <i>bank offset</i>]]	Reserves <i>size</i> in bytes in the .bss (uninitialised data) section.
.data	Assembles into the .data (initialised data) section.
.sect “ <i>section name</i> ”	Assmebles into a named (initialised) section
.text	Assembles into a .text (executable code) section.
<i>symbol</i> .usect “ <i>section name</i> ”, <i>size in bytes</i> [, <i>alignment</i> [, <i>bank offset</i>]]	Reserves <i>size</i> in bytes in a named (uninitialised) section.
.space	Reserves a block of bytes.
.cstring { <i>expr₁</i> “ <i>string₁</i> ”}[, ..., { <i>expr_n</i> “ <i>string_n</i> ”}]	Initialises one or more text strings.
.double <i>value₁</i> [, ..., <i>value_n</i>]	Initialises one or more 64-bit, IEEE double-precision floating-point numbers.
.field <i>value</i> [, <i>size</i>]	Initialises a field of <i>size</i> bits (1-32) with <i>value</i> .
.float <i>value₁</i> [, ..., <i>value_n</i>]	Initialises one or more 32-bit, IEEE, single-precision floating-point numbers.
.half <i>value₁</i> [, ..., <i>value_n</i>]	Initialises one or more 16-bit integers (half-word).
.int <i>value₁</i> [, ..., <i>value_n</i>]	Initialises one or more 32-bit integers.
.long <i>value₁</i> [, ..., <i>value_n</i>]	Initialises one or more 32-bit integers.
.short <i>value₁</i> [, ..., <i>value_n</i>]	Initialises one or more 16-bit integers (half-word).
.string { <i>expr₁</i> “ <i>string₁</i> ”}[, ..., { <i>expr_n</i> “ <i>string_n</i> ”}]	Initialises one or more text strings.
.ubyte <i>value₁</i> [, ..., <i>value_n</i>]	Initialises one or more successive unsigned bytes in the current section.
.uchar <i>value₁</i> [, ..., <i>value_n</i>]	Initialises one or more successive unsigned bytes in the current section, but it is mainly use for ASCII characters.
.uhalf <i>value₁</i> [, ..., <i>value_n</i>]	Initialises one or more unsigned 16-bit integers (half-word).
.uint <i>value₁</i> [, ..., <i>value_n</i>]	Initialises one or more unsigned 32-bit integers.
.ulong <i>value₁</i> [, ..., <i>value_n</i>]	Initialises one or more unsigned 32-bit integers.
.ushort <i>value₁</i> [, ..., <i>value_n</i>]	Initialises one or more unsigned 16-bit integers (half-word).
.uword <i>value₁</i> [, ..., <i>value_n</i>]	Initialises one or more unsigned 32-bit integers.
.word <i>value₁</i> [, ..., <i>value_n</i>]	Initialises one or more 32-bit integers.

The SRAM can only hold data, while the code section can hold both instructions and data.

10.2.1 Example 1

In this example, code is assembled into the .data and .text sections.

```
1          ****
2          ** Reserve space in .data.      **
3          ****
4 00000000          .data
5 00000000          .space 0CCh
6
7          ****
8          ** Assemble into .text.      **
9          ****
10 00000000         .text           ; Constant into .data
11     00000000 INDEX    .set    0
12 00000000 E3A00000      MOV     R0, #INDEX
13
14          ****
15          ** Assemble into .data.      **
16          ****
17 000000cc          Table: .data
18 000000cc FFFFFFFF      .word   -1       ; Assemble 32-bit
19                           ; constant into .data.
20
21 000000d0 FF          .byte   0FFh     ; Assemble 8-bit
22                           ; constant into .data.
23
24          ****
25          ** Assemble into .text.      **
26          ****
27 00000004          .text
28 00000004 000000CC" con: .field  Table, 32
29 00000008 E51F100C      LDR     R1, con
30 0000000c E5912000      LDR     R2, [R1]
31 00000010 E0802002      ADD     R2, R0, R2
```

10.2.2 Example 2

This example uses the .int directive to initialise words.

```
1 00000000          .space 73h
2 00000000          .bss   PAGE, 128   ; Reserve 128 bytes for pointer PAGE
3 00000080          .bss   SYMPTR, 4    ; Reserve 4 bytes for pointer SYMPTR
4 00000074 E3A00056 INST: MOV    R0, #056h
5 00000078 0000000A      .int   10, SYMPTR, -1, 35 + 'a', INST, "abc"
  0000007c 00000080-
  00000080 FFFFFFFF
  00000084 00000084
  00000088 00000074'
  0000008c 00000061
  00000090 00000062
  00000094 00000063
```

10.2.3 Example 3

- This example shows how the `.long` directive initialises words.
- The symbol `DAT1` points to the first word that is reserved.

```
1 00000000 0000ABCD  DAT1: .long    0ABCDh, 'A' + 100h, 'g', 'o'  
00000004 00000141  
00000008 00000067  
0000000c 0000006F  
2 00000010 00000000'          .long    DAT1, 0AABBCCDDh  
00000014 ABBCCDD  
3 00000018             DAT2:
```

10.2.4 Example 4

- In this example, the `.word` directive is used to initialise words.
- The symbol `WORDX` points to the first word that is reserved.

```
1 00000000 00000C80  WORDX: .word    3200, 1 + 'AB', -0AFh, 'X'  
00000004 00004242  
00000008 FFFFFF51  
0000000c 00000058
```

10.3 Assembler directives for controlling conditional computations (GCC and ArmClang)

Mnemonic and syntax	Description
<code>.if condition</code>	Assembles code block if the <i>condition</i> is true.
<code>.else</code>	Assembles code block if the <code>.if condition</code> is false. When using the <code>.if</code> construct, the <code>.else</code> construct is optional.
<code>.elseif condition</code>	Assembles code block if the <code>.if condition</code> is false and the <code>.elseif condition</code> is true. When using the <code>.if</code> construct, the <code>.elseif</code> construct is optional.
<code>.endif</code>	Ends <code>.if</code> code block.
<code>.loop [count]</code>	Begins repeatable assembly of a code block. The loop count is determined by the <i>count</i> .
<code>.break [end condition]</code>	Ends <code>.loop</code> assembly if <i>end condition</i> is true. When using the <code>.loop</code> construct, the <code>.break</code> construct is optional.
<code>.endloop</code>	Ends <code>.loop</code> code block.

10.3.1 Example

The example below shows conditional assembly:

Memory for Data			
1	00000001	SYM1	.set 1
2	00000002	SYM2	.set 2
3	00000003	SYM3	.set 3
4	00000004	SYM4	.set 4
5			
Memory for Code			
6	00000000 04	If_4:	.if SYM4 = SYM2 * SYM2 .byte SYM4 ; Equal values
7			.else
8			.byte SYM2 * SYM2 ; Unequal values
9			.endif
10			
11		If_5:	.if SYM1 <= 10 .byte 10 ; Less than / equal
12			.else
13	00000001 0A		.byte SYM1 ; Greater than
14			.endif
15			
16		If_6:	.if SYM3 * SYM2 != SYM4 + SYM2 .byte SYM3 * SYM2 ; Unequal value
17			.else
18			.byte SYM4 + SYM4 ; Equal values
19			.endif
20			
21	00000002 08	If_7:	.if SYM1 = SYM2 .byte SYM1
22			.elseif SYM2 + SYM3 = 5
23			.byte SYM2 + SYM3
24			.endif
25			
26			
27	00000003 05		
28			

10.4 Directive for creating reusable block of codes (GCC and ArmClang)

A macro definition is a series of source statements in the following format:

```
macro_name .macro [parameter_1][, ..., parameter_n]
    model_statements_or_macro_directives
    [.mexit]
    .endm
```

- **macro_name** is the name of the macro. You must place the name in the source statement's label field. Only the first 128 characters of a macro name are significant. The assembler places the macro name in the internal opcode table, replacing any instruction or previous macro definition with the same name.
- **.macro** is the directive that identifies the source statement as the first line of a macro definition. You must place **.macro** in the opcode field.
- **parameter_1, parameter_n** are optional substitution symbols that appear as operands for the **.macro** directive.
- **.mexit** is a directive that functions as a **goto .endm**. The **.mexit** directive is useful when error testing confirms that macro expansion fails and completing the rest of the macro is unnecessary.
- **.endm** is the directive that terminates the macro definition.

10.4.1 Example

Macro definition: The following code defines a macro, **add3**, with 4 parameters:

```
*      add3
*
*      ADDRP = P1 + P2 + P3

add3  .macro P1, P2, P3, ADDRP
      ADD ADDRP, P1, P2
      ADD ADDRP, ADDRP, P3
      .endm
```

Macro call: The following code calls the **add3** macro with 4 arguments.

```
add3 R1, R2, R3, R0
```

Macro expansion: The following code shows the substitution of the macro definition for the macro call. The assembler substitutes **R1**, **R2**, **R3**, and **R0** for the **P1**, **P2**, **P3**, and **ADDRP** parameters of **add3**.

```
ADD R0, R1, R2
ADD R0, R0, R3
```

11 Memory-mapped I/O devices

11.1 Data flow

- Data consists of values, symbols, addresses and instructions.
- Data flows from source memory to destination memory.
- Memory is a space which has:
 - Location
 - Address
 - Label

11.2 Basic unit of input/output data

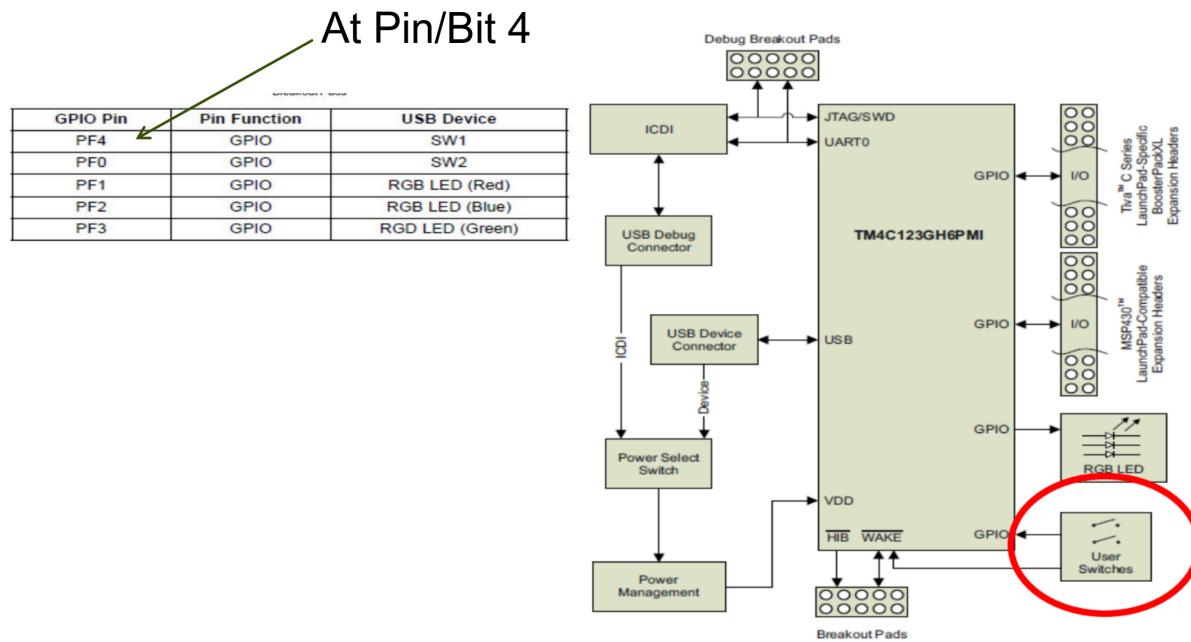

- A port has 8 pins.
- Hence, the basic unit of input/output data is one byte, or 8-bits.
- However, inside ARM Cortex, the data bus transfers 4-bytes or 32-bits per cycle.

11.3 Memory allocation

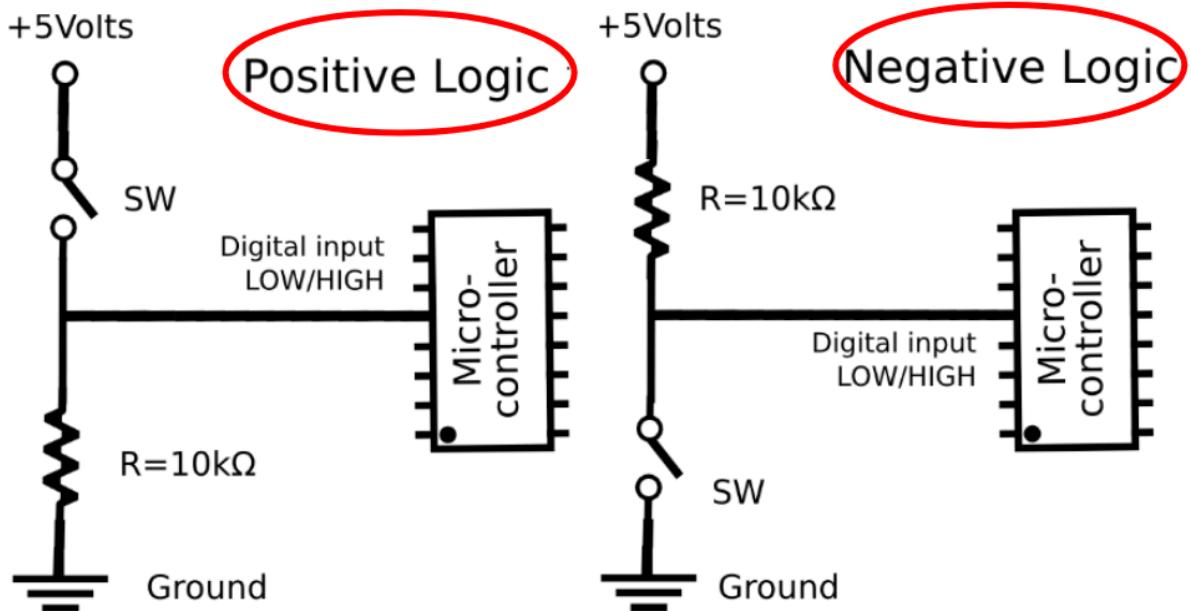

- Think of memory as a vector, like `memory[address]`.
- To store **variable** values, assign a memory label to a variable value, which indicates:
 - A fixed memory address, which is **useful** to users.
 - Multiple instances of a value, which is **needed** by users.
 - Example:
`TravelledDistance DCD 0`
- To store **fixed** values, assign a memory label to a fixed value, which indicates:
 - Multiple memory addresses, which is **not useful** to users.
 - Single instance of value, which is **needed** by users.
 - Example:
`GravityAcceleration EQU 9.8`

11.4 Example of internal data input from port F

Address of port F's data is R4 = 0x40025FFF.

Types of logic switches:

Sample code:

```
loop          BL  SSR_On   ; Call the function to switch on the LED

waitForpress1
    ; Read the status of the port PF4
    LDR R0, [R4]

    ; Check if the button is pressed
    CMP R0, #0x10

    ; Continue the loop if the button is not pressed
    BEQ waitForpress1

waitForrelease1
    ; Read the status of the port PF4
    LDR R0, [R4]

    ; Check if the button is released
    CMP R0, #0x10

    ; Continue the loop if the button is not released
    BNE waitForrelease1

    ; Call the function to switch off the LED
    BL SSR_Off

; Function to switch on LED
waitForpress2
    ; Read the status of the port PF4
    LDR R0, [R4]

    ; Check if the button is pressed
    CMP R0, #0x01

    ; Continue the loop if the button is not pressed
    BEQ waitForpress2

waitForrelease1
    ; Read the status of the port PF4
    LDR R0, [R4]

    ; Check if the button is released
    CMP R0, #0x01

    ; Continue the loop if the button is not released
    BNE waitForrelease2

    ; Go back to the start to run an infinite loop
    B loop
```

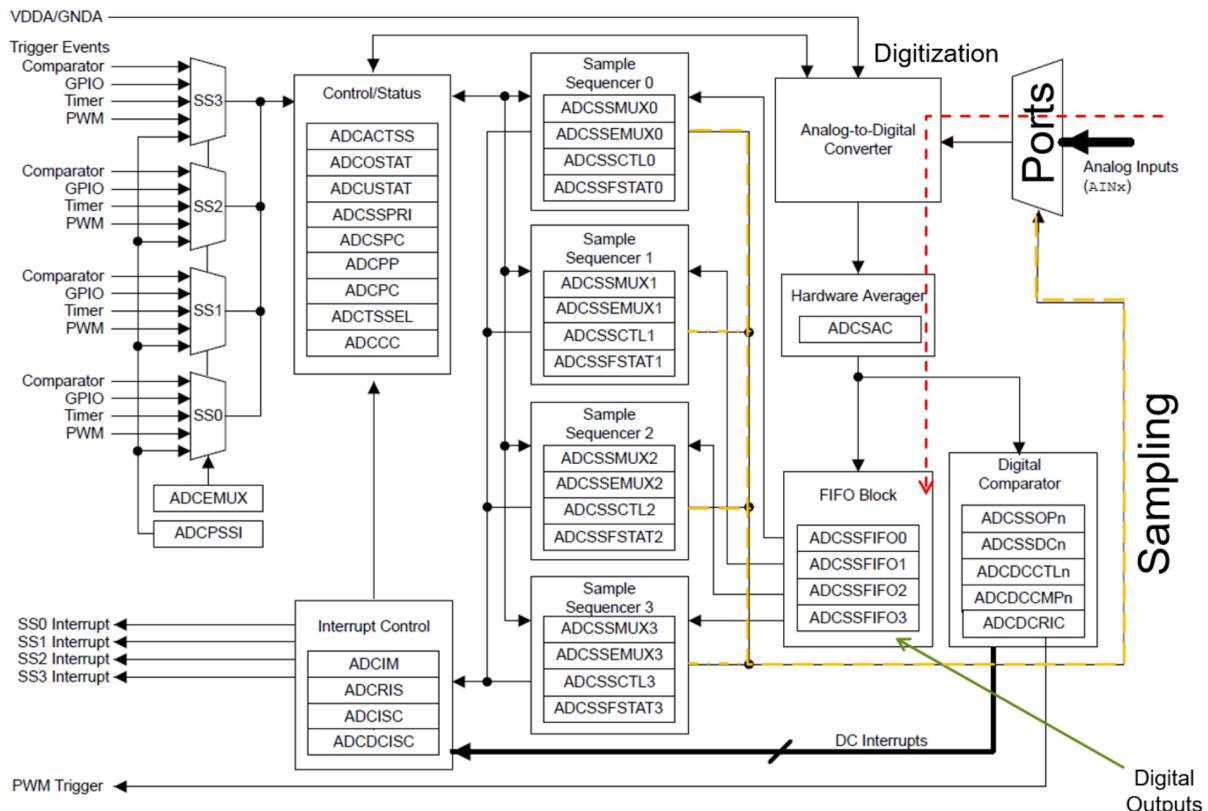

11.5 TM4C123G GPIO module

- Each GPIO port is a separate hardware instantiation of the same physical block.
- The TM4C123G allows for one interrupt per port.

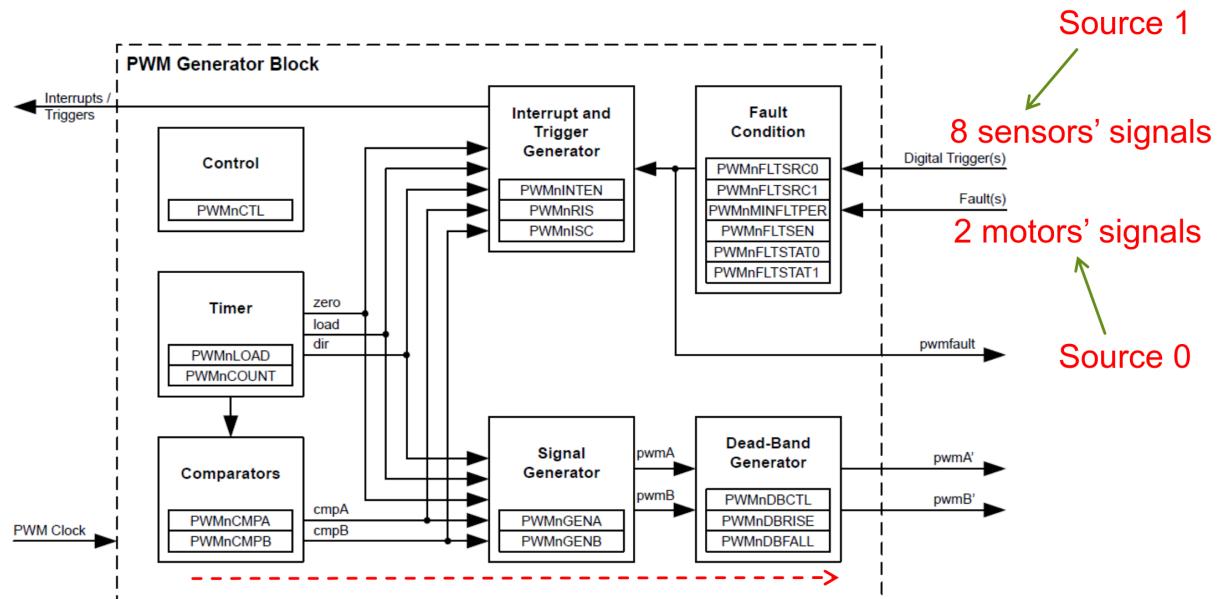

11.6 TM4C123G ADC module

Note that some pins can receive analogue values.

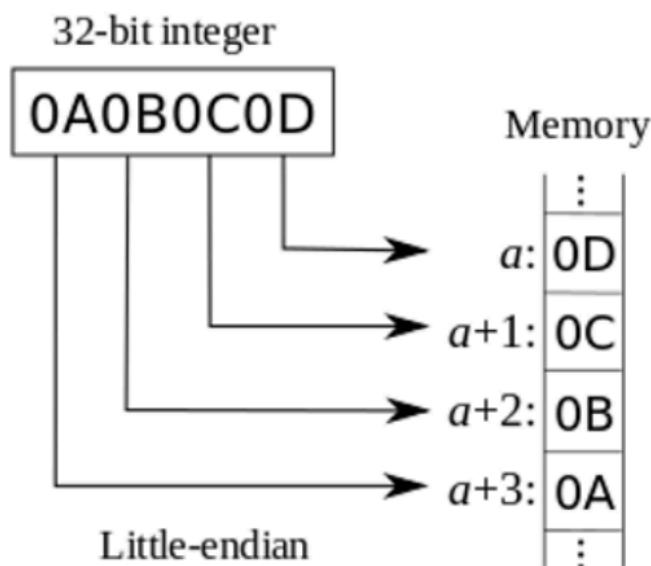

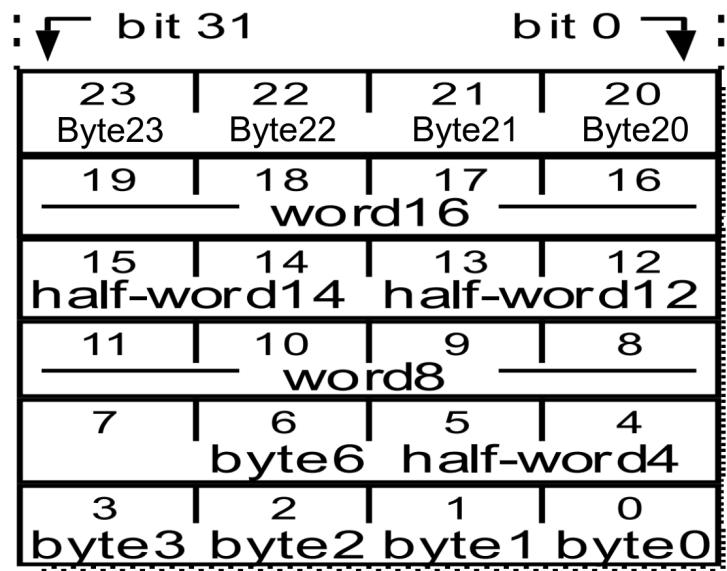

11.7 TM4C123G PWM module

TM4C123G has two PWM modules, and 4 PWM generators per module.

11.8 Data organisation nomenclature

- Data is organised into 8-bits or one byte, which is the basic unit of data.
- Data organised into 16-bits is called a half-word.
- Data organised into 32-bits is called a word.
- The size of a word depends on the size of the address bus. A 32-bit address bus would be able to handle 32-bit data.
- ARM Cortex is a 32-bit microcontroller, so a word is 32-bits.
- A memory unit in hardware is 1-byte, while a memory unit in software is 4-bytes by default.

11.9 Address indexing methods

The addressing mode is formed from two parts:

- The base register.
- The offset.

The base register can be any one of the general-purpose registers (R0 - R16), including the program counter register (PC), which allows for PC-relative addressing for position-independent code.

The offset takes one of three formats:

1. Intermediate

The offset is an unsigned number that can be added to or subtracted from the base register.

Immediate offset addressing is useful for accessing data elements that are a fixed distance from the start of the data object, such as structure fields, stack offsets and input/output registers.

For the word and unsigned byte instructions, the immediate offset is a 12-bit number. For the half-word and signed byte instructions, it is an 8-bit number.

2. Register

The offset is a general-purpose register (not the program counter, PC) that can be added to or subtracted from the base register. Register offsets are useful for accessing arrays or blocks of data.

3. Scaled register

The offset is a general-purpose register (not the program counter, PC) shifted by an immediate value, then added to or subtracted from the base register. The same shift operations used for data-processing instructions can be used (Logical Shift Left, Logical Shift Right, Arithmetic Shift Right and Rotate Right), but Logical Shift Left is the most useful as it allows an array indexed to be scaled by the size of each array element.

Scaled register offsets are only available for the word and unsigned byte instructions.

Types of address indexing:

- Offset, where the base register and offset are added or subtracted to form the memory address.
- Pre-indexed, where the base register and offset are added or subtracted to form the memory address. The base register is then updated with this new address, to allow automatic indexing through an array or memory block.
- Post-indexed, where the value of the base register alone is used as the memory address. The base register and offset are added or subtracted, and this value is stored back in the base register to allow automatic indexing through an array or memory block.

11.9.1 Pre-indexing without write-back

Pre-indexing without write-back is to use [base + offset] and **not update** the base address afterwards.

- Data: memory[base + offset]
- Base address register is **not updated**
- Code:

```
LDR R0, [R1, #4] ; C equivalent: R0 = memory[R1 + 4]
```

11.9.2 Pre-indexing with write-back

Pre-indexing without write-back is to use [base + offset] and **update** the base address afterwards.

- Data: memory[base + offset]
- Base address register: base + offset
- Code:

```
LDR R0, [R1, #4]! ; C equivalent: R0 = memory[R1 + 4]; R1 = R1 + 4
```

11.9.3 Post-indexing

Post-indexing is to use [base] and update the base address **before** using it.

- Data: memory[base]
- Base address register: base + offset
- Code:

```
LDR R0, [R1], #4 ; C equivalent: R1 = R1 + 4; R0 = memory[R1]
```

11.9.4 Example 1: Pre-indexed address without write-back

```
LDR R11, [R1, R2] ; Load R11 from the address in R1 + R2  
STRB R10, [R7, -R4] ; Store byte from R10 to the address in R7 - R4
```

11.9.5 Example 2: Pre-indexed address with write-back

```
LDR R11, [R3, R5, LSL #2] ; Load R11 from the address in R3 + (R5 * 4)  
LDR R1, [R0, #4]! ; Load R1 from R0 + 4, then R0 = R0 + 4  
STRB R10, [R7, #-1]! ; Store byte from R7 to R6 - 1, then R6 = R6 - 1
```

11.10 ARM Cortex M4 GPIO ports

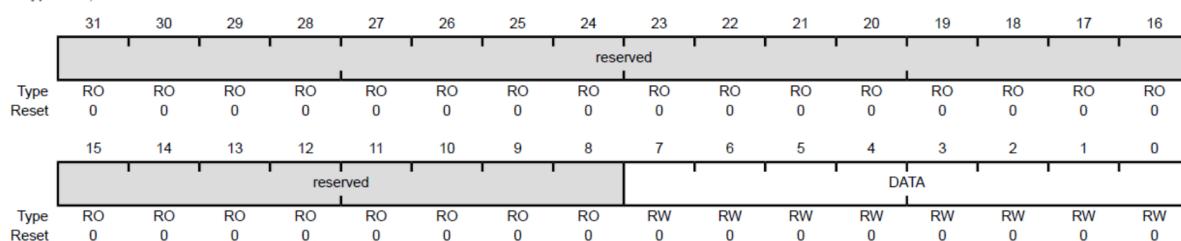

- ARM Cortex M4 has 6 maskable data registers (ports A to F).
- Note that the last 12 bits in the GPIO ports are not used for the address. They are instead used to make input and output data. By default, use you choose the offset of 0xFFFF.

GPIO Data (GPIOData)

```

GPIO Port A (APB) base: 0x4000.4000
GPIO Port A (AHB) base: 0x4005.8000
GPIO Port B (APB) base: 0x4000.5000
GPIO Port B (AHB) base: 0x4005.9000
GPIO Port C (APB) base: 0x4000.6000
GPIO Port C (AHB) base: 0x4005.A000
GPIO Port D (APB) base: 0x4000.7000
GPIO Port D (AHB) base: 0x4005.B000
GPIO Port E (APB) base: 0x4002.4000
GPIO Port E (AHB) base: 0x4005.C000
GPIO Port F (APB) base: 0x4002.5000
GPIO Port F (AHB) base: 0x4005.D000
Offset 0x000
Type RW, reset 0x0000.0000

```

- Bits 8 to 31 are reserved and are read-only. Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
- Bits 0 to 7 are GPIO data bits and are read-write. The register is virtually mapped to 256 locations in the address space. To facilitate the reading and writing of data to these registers by independent drivers, the data read from and written to the registers are masked by the eight address lines, bits 2 to 9. Reads from this register return its current state. Writes to this register only affect bits that are not masked by bits 2 to 9 and are configured as outputs.

11.10.1 Read and write example

Figure 10-3. GPIOData Write Example

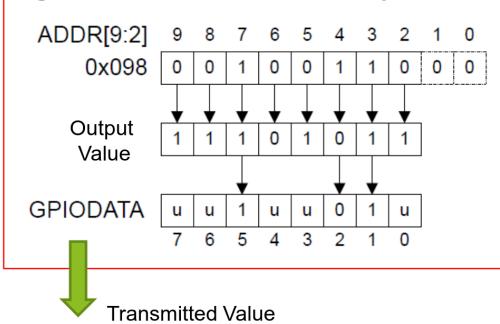

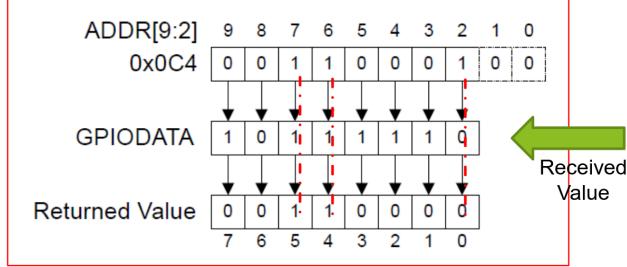

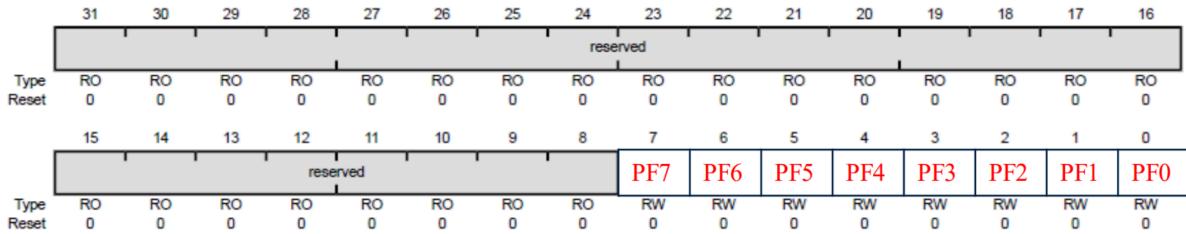

Figure 10-4. GPIOData Read Example

11.10.2 Example with port F

GPIO Data Port F address: 0x40025000

```

PORT_F_PIN_0 EQU 0x40025 004 ; ADR[9:0] = 0 000 0100
PORT_F_PIN_1 EQU 0x40025 008 ; ADR[9:0] = 0 000 1000
PORT_F_PIN_2 EQU 0x40025 010 ; ADR[9:0] = 0 001 0000
PORT_F_PIN_3 EQU 0x40025 020 ; ADR[9:0] = 0 010 0000

```

Masking port F:

This mask will result in an address of 0x40025038, which represents port F pins 1-3, as 0000 0011 1000 in binary is 038 in hexadecimal.

Port F pins:

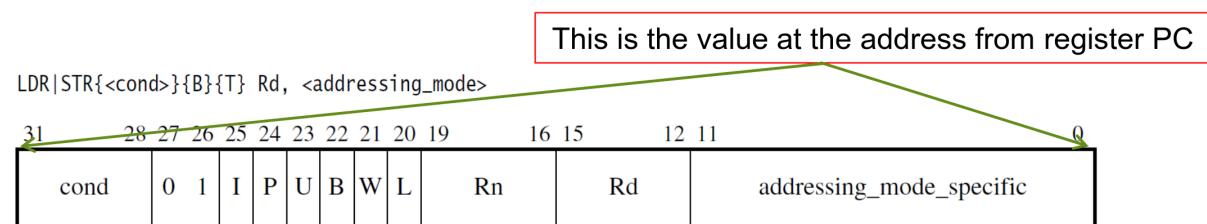

Port F register at 0x40025 000												
	2^{11}	2^{10}	2^9	2^8	2^7	2^6	2^5	2^4	2^3	2^2	2^1	2^0
0x38	0	0	0	0	0	0	0	0	0	1	X	X
	0	0	0	0	0	0	0	0	1	0	X	X
	0	0	0	0	0	0	0	1	0	0	X	X
	0	0	0	0	0	0	1	0	0	0	X	X

11.11 Encoding of instructions in ARM

11.11.1 LDR and STR instructions for data I/O

- Load instructions load a single value from memory and write it to a general-purpose register.
- Store instructions read a value from a general-purpose register and store it to memory.
- Load (input to ALU) and store (output) words and unsigned bytes.

Where:

- I, P, U and W are bits that distinguish between different types of <addressing_mode>.
- L bit distinguishes between a load (L = 1) and a store instruction (L = 0)
- B bit distinguishes between an unsigned byte (B = 1) and a word (B = 0) access.
- Rn specifies the base register used by <addressing_mode>.
- Rd specifies the register whose contents are to be loaded or stored.

11.11.1.1 For sizes other than a word

Load (input to ALU) and store (output from ALU) **half-words, double-words, or unsigned bytes.**

LDR|STR{<cond>}D|H|SH|SB Rd, <addressing_mode>

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	8	7	6	5	4	3	0
cond	0	0	0	P	U	I	W	L		Rn		Rd		addr_mode	1	S	H	1	addr_mode		

Where:

- `addr_mode` are addressing mode specific bits.
- `I`, `P`, `U` and `W` are bits that specify the type of addressing mode.
- `L`, `S` and `H` are bits that combine to specify signed or unsigned loads or stores, as well as double-word, half-word or byte accesses.
- `Rn` specifies the base register used by the addressing mode.
- `Rd` specifies the register whose contents are to be loaded or stored.

12 Digital input and output (GPIO)

12.1 Digital signals

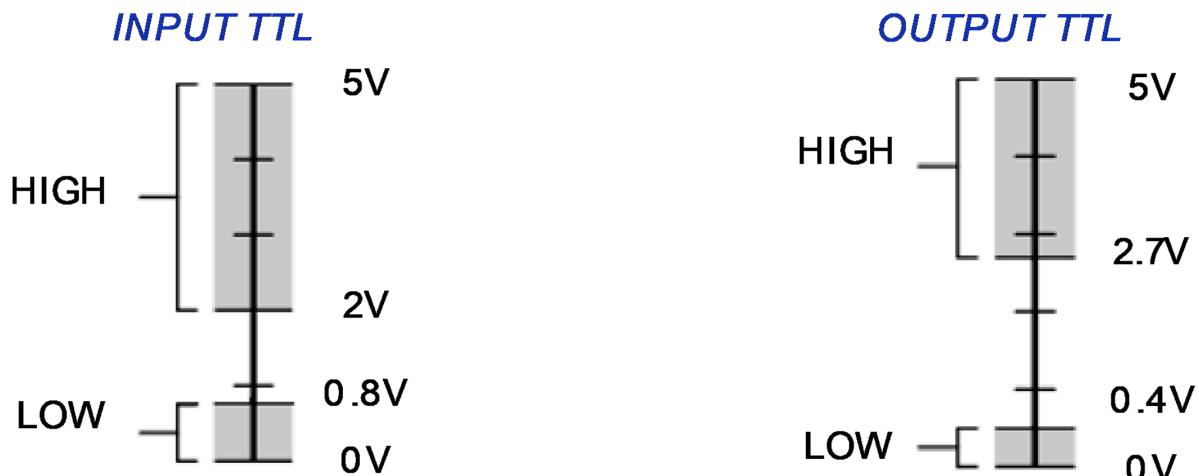

12.1.1 Logic levels

Logic	Voltage
0	0 V
1	5 V

12.1.2 Transistor-transistor logic (TTL) levels

V_{OH}	The minimum output voltage level a TTL device will provide for a HIGH signal.
V_{IH}	The minimum input voltage level to be considered a HIGH.
V_{OL}	The maximum output voltage level a device will provide for a LOW signal.
V_{IL}	The maximum input voltage level to still be considered a LOW.

12.1.3 Acceptable input digital signals (TTL levels)

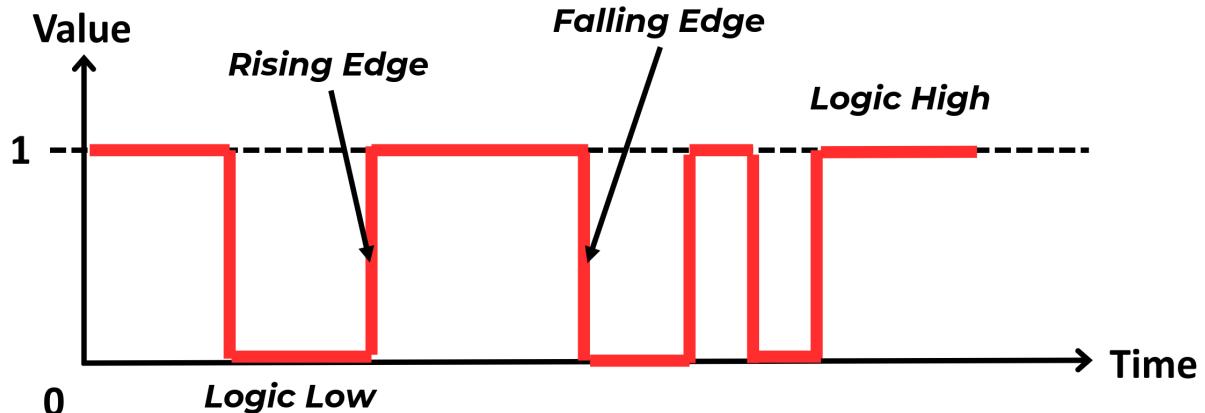

12.1.4 Representation and events of digital signals

Representation:

- Time series of 1s and 0s.
- Time series of square waves.

Events:

- Rising edge
- Falling edge
- Level of logic high
- Level of logic low

12.1.5 Signal lines of digital signals

- These are physical wires which transmit digital signals from one end to another end.
- When a microcontroller (MCU) or device sends out a digital signal through a signal line to be HIGH or LOW, such an operation is called a digital output.

12.1.6 Tri-state logic

- In digital devices a device, which can output 1, 0, or high impedance to signal lines, is called a tri-state device.
- Three-state, tri-state, or 3 state logic allows an output or input pin to assume a high impedance state.
- This effectively removes the output from the circuit, in addition to the 0 and 1 logic levels.
 - This is needed if more than 2 devices are sharing the same signal.
 - This allows multiple devices to share the same output lines.

12.1.7 Schmitt filters or triggers

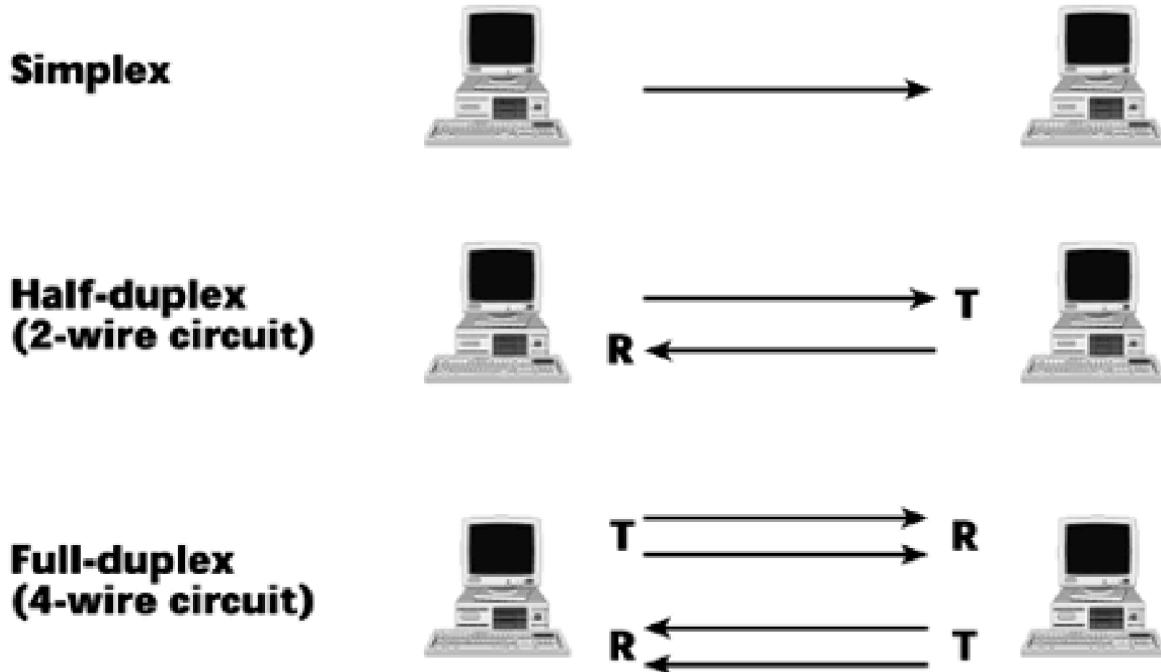

- Digital signals can be contaminated by noises due to various reasons.
- The input of digital signals at the receiver must have the ability to filter out the noises. One type of device for such purpose is called a Schmitt filter or trigger.

12.1.8 Principle of Schmitt filters

- If $V_{in} > V_{max}$, then the output logic is HIGH.
- If $V_{in} < V_{min}$, then the output logic is LOW.

12.1.9 Communication of digital signals

- Asynchronous serial output
- Synchronous serial output

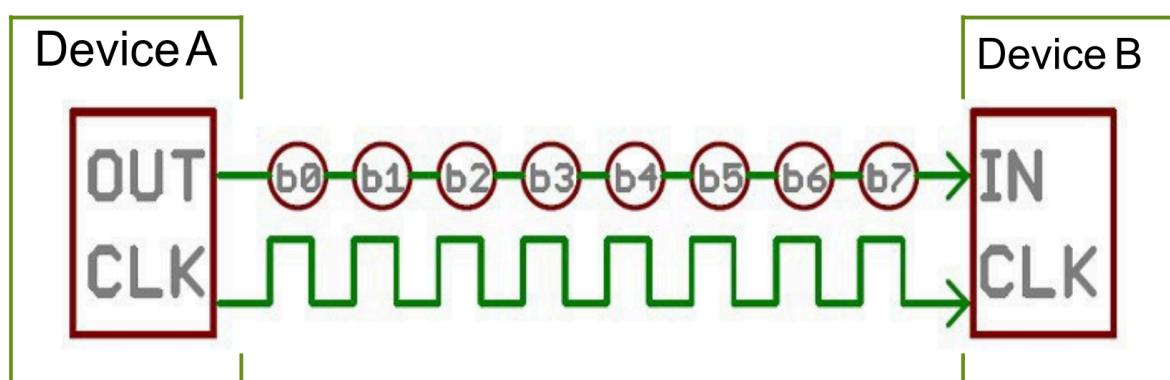

12.2 Synchronous digital input and output

12.2.1 Working principle of synchronous serial input and output

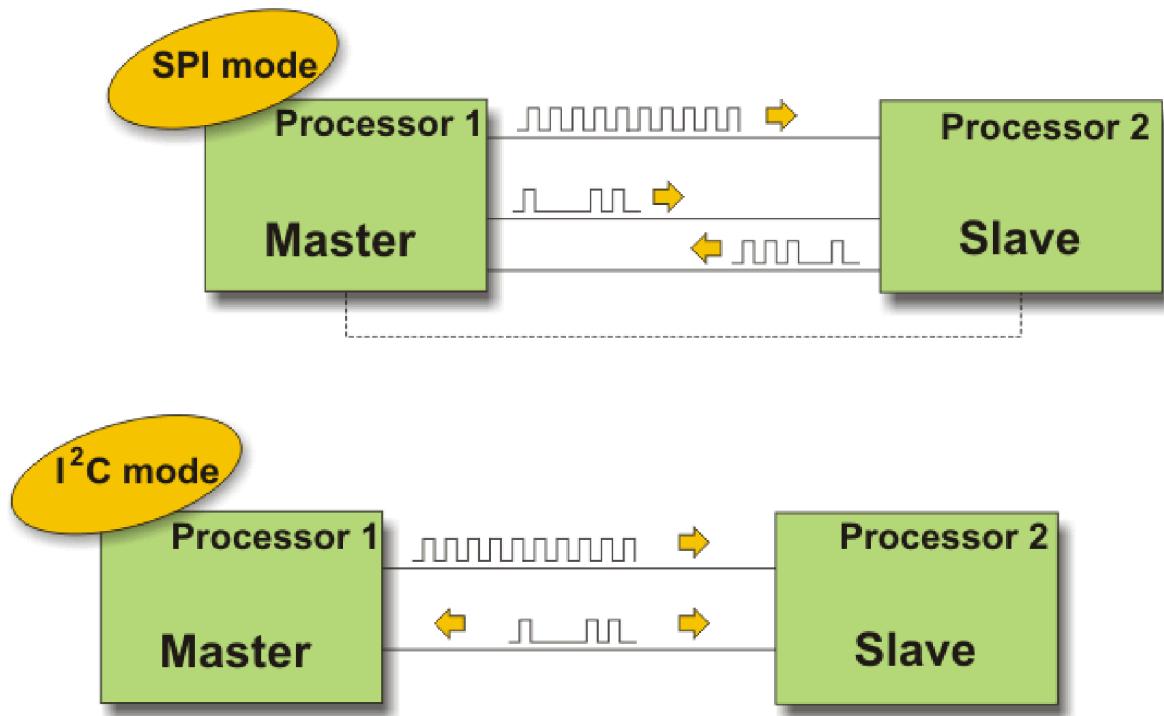

The input unit consists of:

- Shift registers
- Data registers
- Control registers
- Status registers
- Data line, clock line

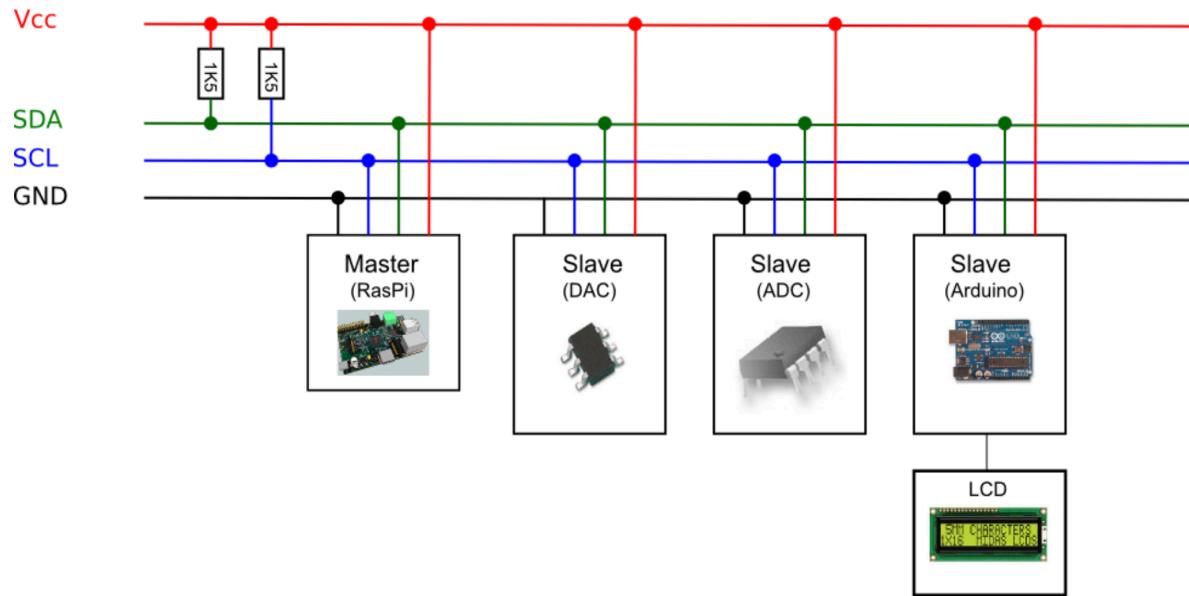

- Frame sync signal send start-pulse which tells the clock line to produce eight clock pulses.
- Each clock pulse causes one bit to be shifted into the receiver (Device B).
- Frame sync signal sends stop-pulse, and the content of the shift register is copied to the data register.

12.2.2 SPI and I²C example

12.2.3 Example of an I²C bus

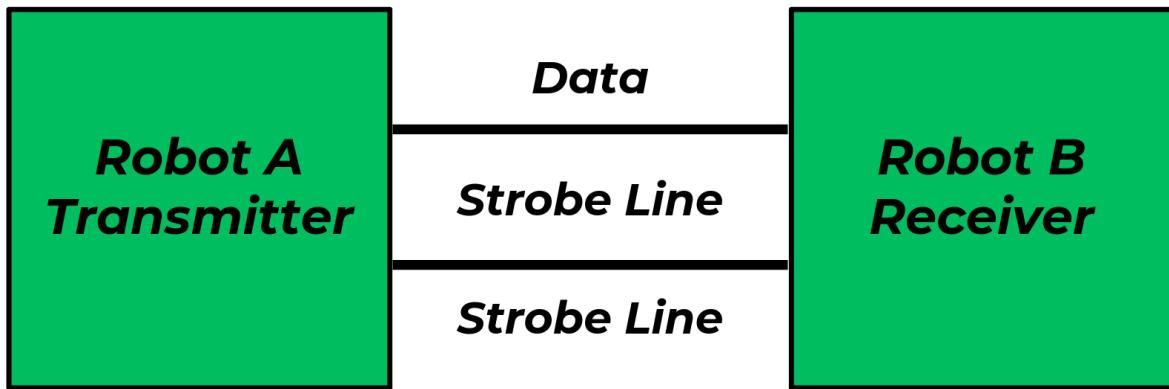

Where:

- SDA refers to Serial Data
- SCL refers to Serial Clock

12.2.4 Working principle of synchronous parallel input and output

The input unit consists of:

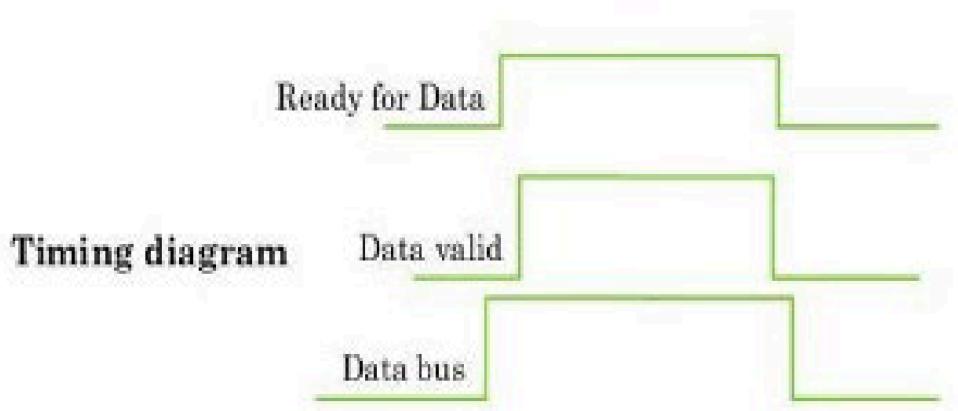

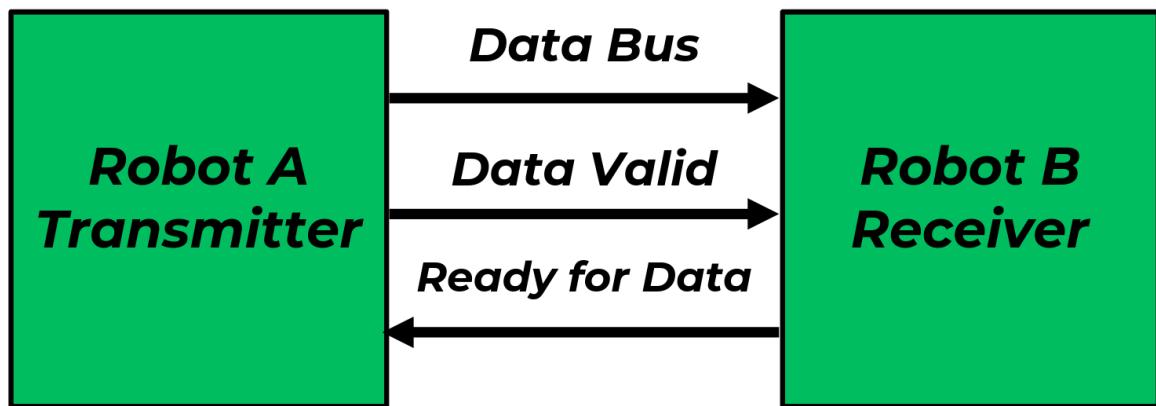

- Data registers
- Control registers
- Status registers
- Input port (8 pins, 1 byte)
- Strobe lines

If the receiver initiates the communication, it first indicates that the receiver is ready to input one byte. The transmitter then sends one byte to the data bus and indicates that one byte is ready to be read. The receiver inputs one byte from the data bus. ([Suitable for reading sensory input](#)).

If the transmitter initiates the communication, it sends one byte to the data bus and indicates that one byte is ready to be read. The receiver inputs one byte from the data bus ([Suitable for sending commands to motors](#)).

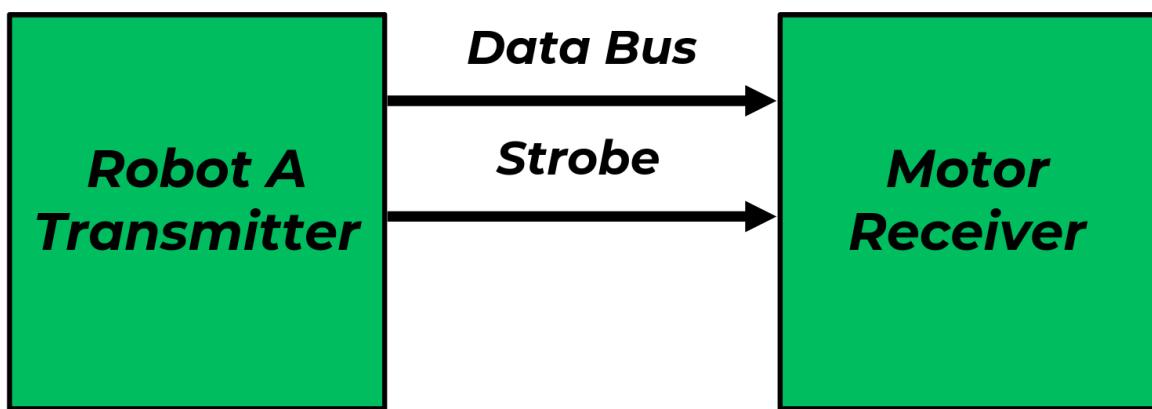

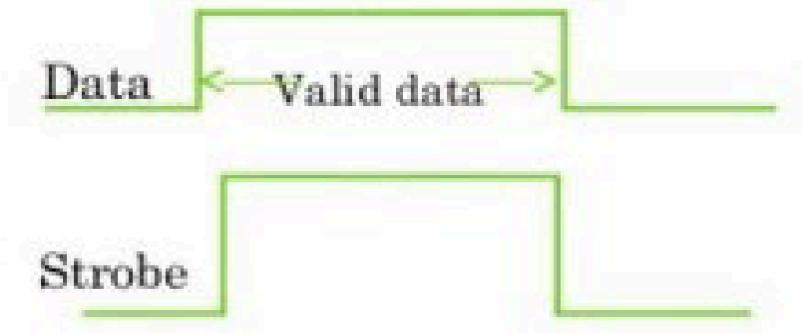

12.2.5 Receiver initiated parallel input

- Receiver first initiates that it is ready to get input.
- Transmitter sends a byte to the data bus.
- Transmitter indicates that one byte is ready on the bus.
- Receiver inputs one byte.
- The process repeats.

12.2.6 Transmitter initiated parallel input

Timing diagram

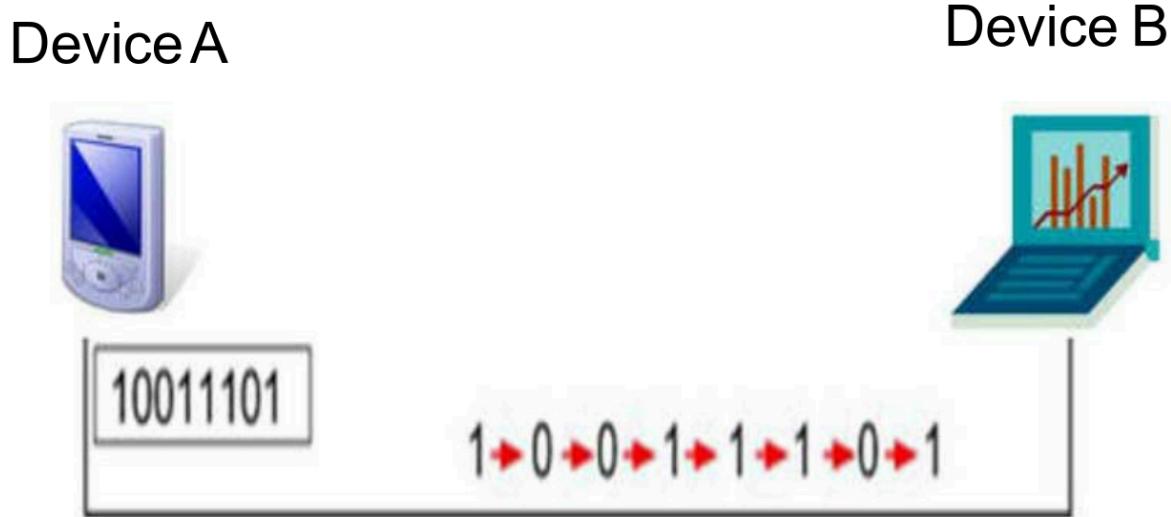

- Transmitter sends a byte to the data bus.
- Transmitter indicates that one byte is ready on the bus.
- Receiver inputs one byte.
- The process repeats.

12.3 Asynchronous digital input and output

12.3.1 Working principle of asynchronous digital input and output (data line)

The input unit consists of:

- Shift registers
- Latch registers
- Control registers
- Status registers
- Data line

- One byte is used for formatted additional bits, such as START bits, STOP bits and parity bits.
- Transmitter and receiver are configured to be running at the same clock frequency.
- The communication is initiated by the transmitter and is triggered by the START bit.
- The START bit wakes up the receiver which will receive the series of bits until the last stop bit.
The data is then latched into the latch register.

12.3.2 Working principle of asynchronous digital input and output (data line)

The input units consist of:

- Data registers
- Control registers
- Status registers
- Input port (8 pins, 1 byte)

	R/W (x)	Features							
PORTA	RA7	RA6	RA5	RA4	RA3	RA2	RA1	RA0	Bit name
	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	

	R/W (1)	Features							
TRISA	TRISA7	TRISA6	TRISA5	TRISA4	TRISA3	TRISA2	TRISA1	TRISA0	Bit name
	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	

Legend

R/W	Readable/Writable bit
(x)	After reset, bit is unknown
(1)	After reset, bit is set

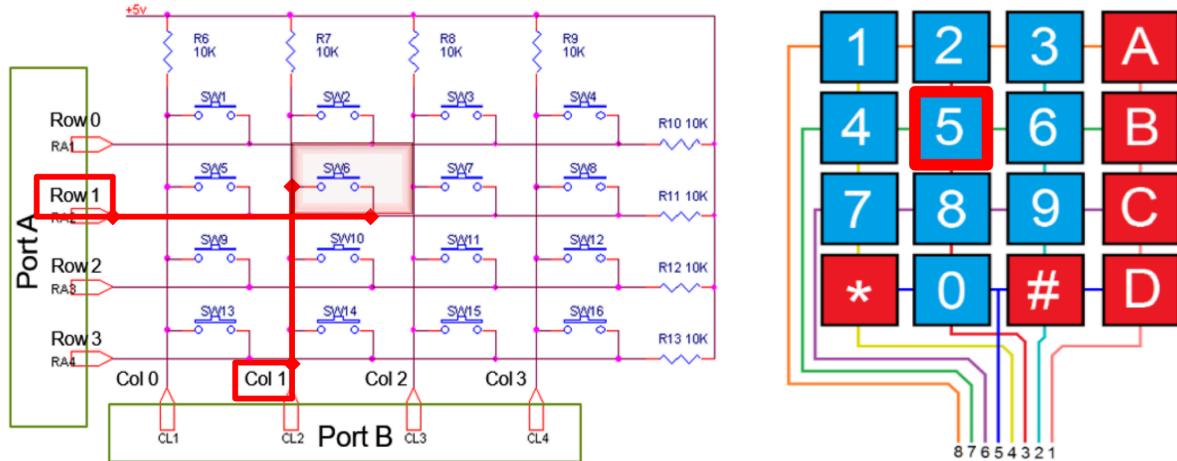

The CPU uses the control registers to configure the input port.

- The tri-state register (TRIS), controls the direction of pins in the input and output port.
- The CPU reads one byte from the input port.
- The CPU decodes the content.
- The CPU acts according to the content.

12.3.2.1 Example: Keypad

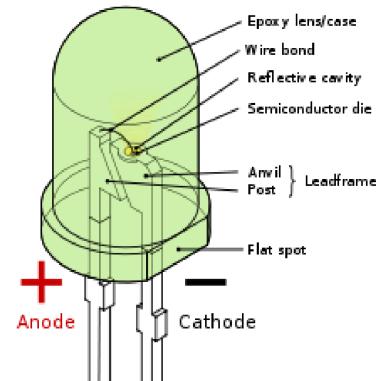

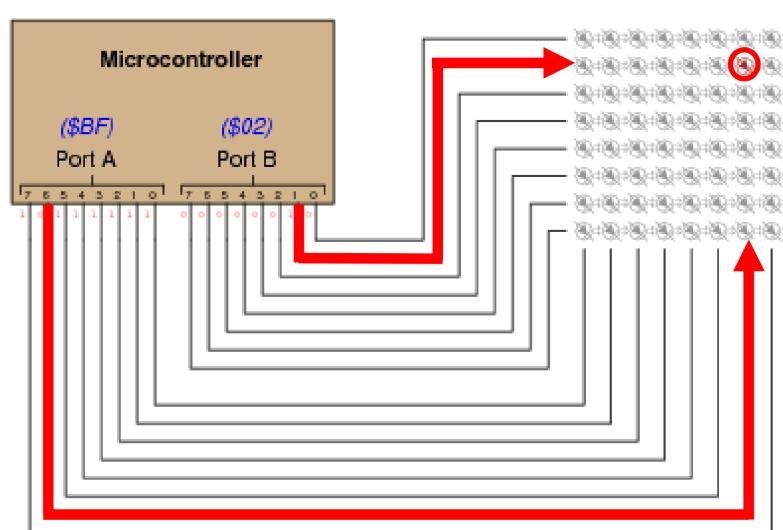

- The CPU sequentially outputs 1110, 1101, 1101, 0111 to port A.
- The CPU inputs data from port B.
- By default, all keys are not pressed.
- When a key is pressed, the corresponding column line will be in logic low (i.e. “0”).

When port A is 1101, and port B is 1101, the keypad registers 5.

12.3.2.2 Example: LED dot matrix

- CPU outputs \$BF (0xBF) to port A and \$02 (0x02) to port B.
- The LED at row 1 and column 6 will light up.

13 Analogue input and outputs

13.1 Types of analogue inputs

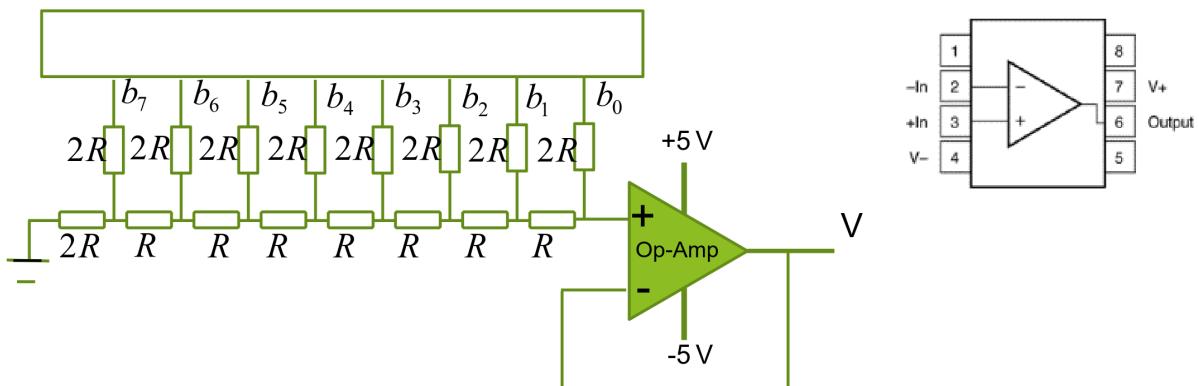

1. Visual
2. Auditory
3. Motion

13.2 Types of analogue outputs

1. Lights or displays
2. Sounds
3. Motion, motors and sensors

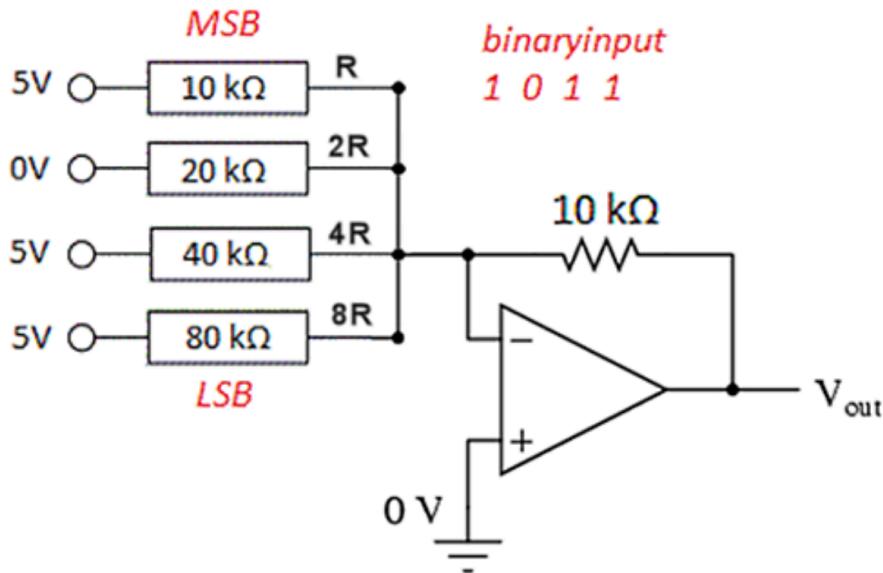

13.3 Working principle of a digital to analogue converter (DAC)

1. Configure the digital to analogue converter.
 2. Read a digital number.
 3. Convert the digital number into an analogue value.
 4. Output the result.
- The digital to analogue converter has data registers, control registers and status registers.
 - After configuration, the digital to analogue converter reads a digital number from the data register.
 - The data register is connected to a network of resistors.
 - The output voltage from the resistor network is connected to an operational amplifier (op-amp).
 - The voltage output from the operational amplifier is the analogue output value.

13.3.1 Exercise

A 4-bit DAC converts these digital numbers into analogue voltages. If we use the circuit shown below, what is the analogue voltage if the digital value is 1011?

$$V_{\text{out}} = -10k \times \left(\frac{5}{10k} + \frac{0}{20k} + \frac{5}{40k} + \frac{5}{80k} \right)$$

$$V_{\text{out}} = -5 + 0 + \frac{5}{4} + \frac{5}{8}$$

$$V_{\text{out}} = -5 + 1.25 + 0.625$$

$$V_{\text{out}} = -6.875 \text{ V}$$

13.4 Specification of DACs

- Range of input value: N bits
- Range of output value: V_{min} (V) to V_{max} (V)
- DAC's digital resolution:

$$\text{Digital resolution} = \frac{\text{Analogue Range}}{\text{Digital Range}}$$

- DAC's analogue resolution:

$$\text{Digital resolution} = \frac{\text{Digital Range}}{\text{Analogue Range}}$$

13.4.1 Exercise

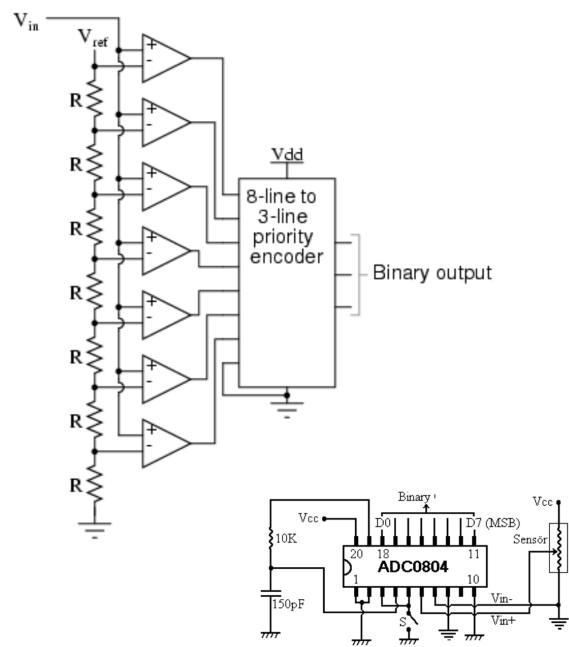

A microcontroller's DAC takes 12-bit numbers as input and produces an analogue output which varies from 0.0 V to 5.0 V. What is the DAC's digital and analogue resolution?

$$\text{Digital resolution} = \frac{5.0 - 0.0}{2^{12}} = 1.2 \times 10^{-3} \text{ V bits}^{-1}$$

$$\text{Analogue resolution} = \frac{2^{12}}{5.0 - 0.0} = 819 \text{ bits V}^{-1}$$

13.5 Working principle of an analogue to digital converter (ADC)

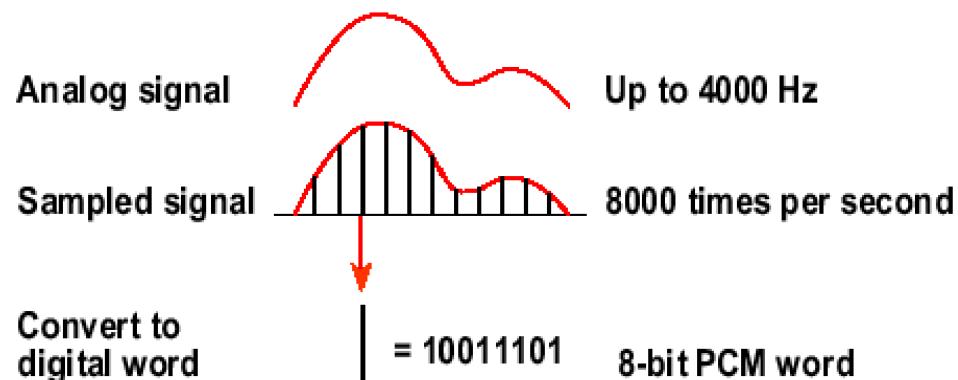

- The analogue to digital converter has data registers, control registers and status registers.
- After configuration, the analogue to digital converter runs a counter which incrementally outputs a digital number.
- The digital number is converted to an analogue voltage by a digital to analogue converter.
- The digital to analogue voltage is compared with the input's analogue voltage.
- When the above two voltages are equal, the analogue to digital converter stops the counter.
- The digital number of the counter is the output of the analogue to digital converter.

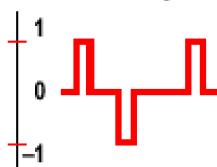

13.5.1 Example: Speech signals

Pulse-code modulation (PCM) is a method used to digitally represent sampled analogue signals. It is the standard form of digital audio in computers.

The 64-kbps voice channel from PCM

8 bits X 8000 samples = 64 Kbps = a digital voice channel

MEMS microphones produce an electrical signal from the change in capacitance caused by the movement of a membrane relative to a stationary plate.

13.6 Specification of ADCs

- Range of input value:
 - High reference voltage (V_{refh}) to low reference voltage (V_{refl})
- Range of output value: N bits
- ADC's digital resolution:

$$\text{Digital resolution} = \frac{\text{Analogue Range}}{\text{Digital Range}}$$

- ADC's analogue resolution:

$$\text{Digital resolution} = \frac{\text{Digital Range}}{\text{Analogue Range}}$$

13.6.1 Exercise

A rotary potentiometer outputs voltages which are within the interval of [0.0, 3.0] (V). We use a 12-bit ADC to convert the analogue values of the potentiometer into digital numbers. What is the ADC's digital and analogue resolution?

$$\text{Digital resolution} = \frac{3.3 - 0.0}{2^{12}} = 0.8 \times 10^{-3} \text{ V bits}^{-1}$$

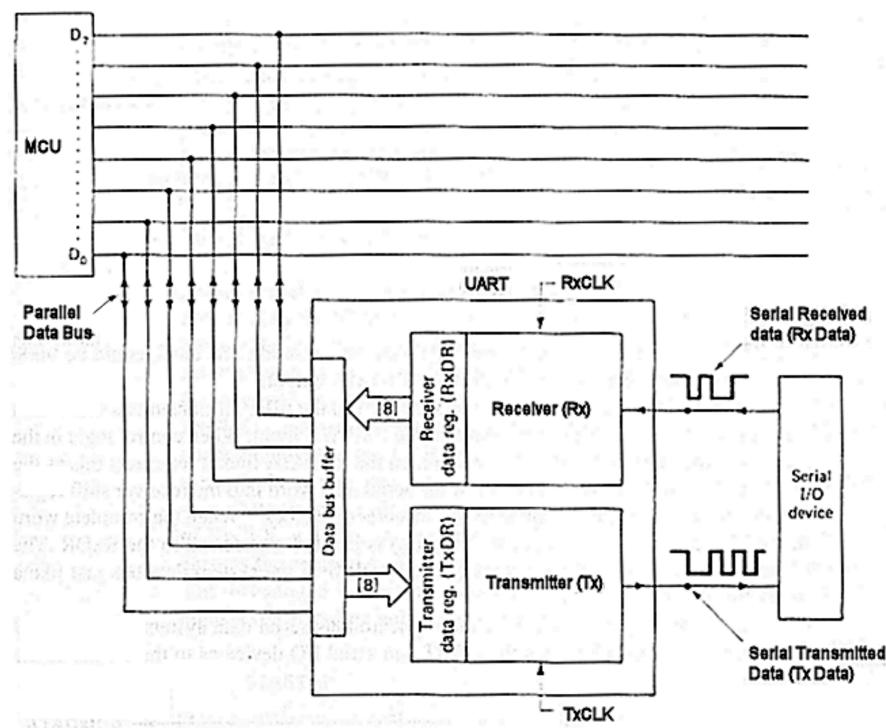

$$\text{Analogue resolution} = \frac{2^{12}}{3.3 - 0.0} = 1241 \text{ bits V}^{-1}$$

14 Universal asynchronous receiver/transmitter (UART)

- UART is the interface device that implements the transmission of serial data between two devices.
- Data terminal equipment (DTE) is the computer.
- Data communication equipment (DCE) is the device, like a modem, printer, etc.
- It is used for serial and parallel conversions for communication between microcontrollers (MCU) and serial I/O devices.
- Its purpose is to translate bytes of data into serial forms suitable for transmitting (TX) and converting the serial data back to bytes of data, or receiving (RX).
- UARTs are commonly included in microcontrollers.
- Data format and transmission speeds are configurable.
- The data format follows the communication standards of EIA, RS232, RS485, etc.
- Communications may be in:
 - Simplex, which is one direction only.
 - Duplex, which is both directions simultaneously.
 - Half duplex, which is RX and TX taking turns, one at a time.
- Has 3 lines, Tx, Rx and ground (GND).

14.1 Basic elements of a parallel/serial interface

- A serial receiver (Rx).
 - It converts a serial format into parallel format, and store it in the receiver data register (RxDR) for eventual transmission to the MCU.
- A serial transmitter (Tx).
 - It takes a parallel word from the transmitter data register (TxDR) and converts it into a serial format for transmission.
- A bidirectional data bus buffer.
 - It passes data from the microcontroller to the transmitter data register, or from the receiver data register to the microcontroller over the system data bus.
- External clocks such as the receiver clock (RxCLK) and the transmitter clock (TxCLK).

14.2 UART connection to external device

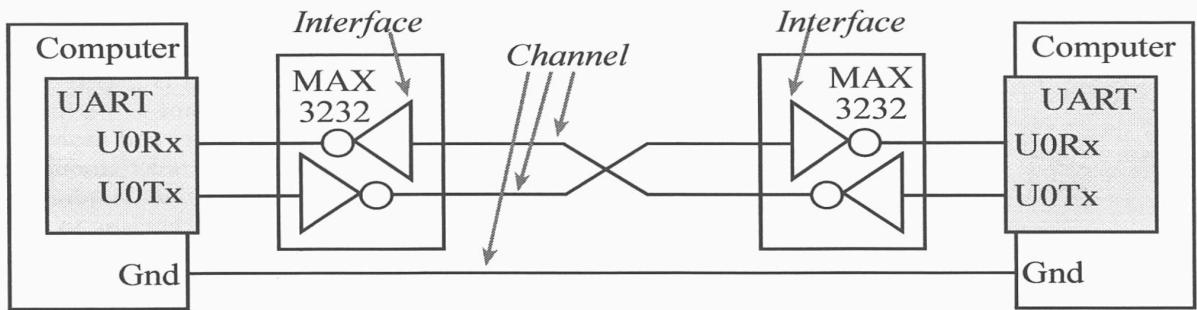

Figure 1: Serial channel connecting two data terminal equipment (DTE) devices.

To improve bandwidth, increase range, and reduce noise, we use the TI MAX3232 chip line driver to bring the voltages to transistor-transistor logic (TTL) requirements.

MAX3232 is a 3 V to 5.5 V multichannel RS-232 line driver/receiver with ± 15 kV ESD protection.

14.3 Data communication (serial)

- Asynchronous communication
 - Transmitter can send data to the receiver at any time.
 - The time delay between the transmission of two words may be indeterminate.
 - Transmitter's clock need not be synchronised with the receiver's clock.
- Synchronous communication
 - Transmitter sends data to receiver continually.
 - Data words are sent in blocks, and separated by sync characters.
 - Sync characters are used by the receiver to synchronise its clock to that of the transmitter.
 - Transmitter sends sync characters continually when there is no data to send.

14.4 Asynchronous serial format (data framing)

- A data frame is a complete and nonvisible packet of information, in bits.
- A data frame includes information, which is data or characters, and overhead, like start, stop, and error checking bits.
- A data frame is the smallest data packet that can be transmitted and understood.

14.4.1 Standard format

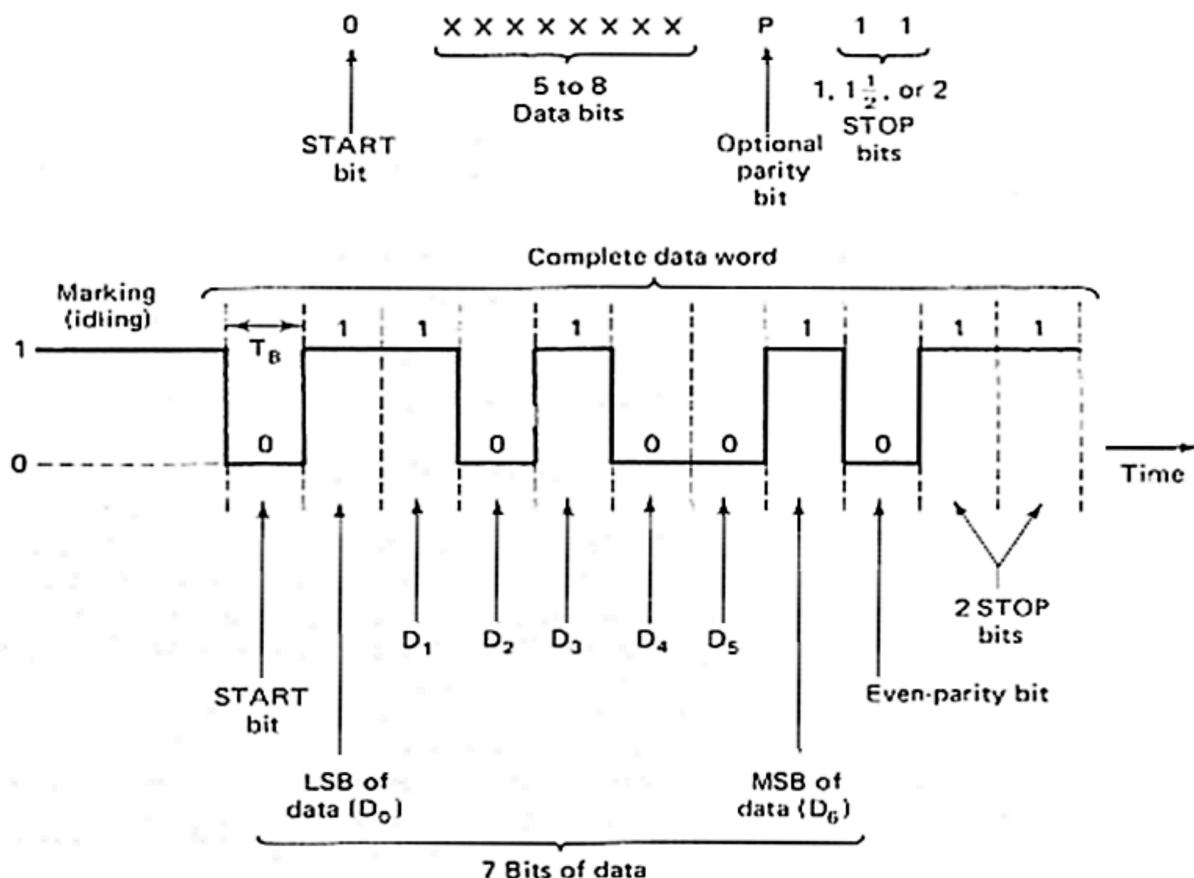

Bit number	1	2	3	4	5	6	7	8	9	10	11
	Start bit	5–8 data bits									Stop bit(s)
	Start	Data 0	Data 1	Data 2	Data 3	Data 4	Data 5	Data 6	Data 7		Stop

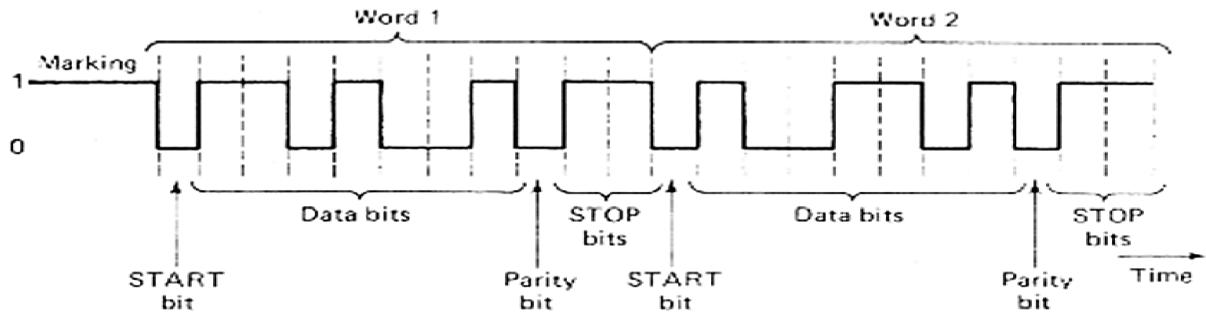

- A START bit at index 0.
- 5 - 8 data bus, and the least significant bit (LSB) is transmitted first.
- Optional parity bit for error detection, which can either be even or odd parity.
- Example of an even parity check:
 - Sum of all bits in 1 transmitter data word must be even.
 - There is an error detected at the receiver if the sum is not even.
 - 7 bit data words, like ASCII, and 1 parity bit:

$\underbrace{1010 \quad 100\color{red}{1}}_{\text{Odd}}$ $\underbrace{1000 \quad 1110}_{\text{Even}}$

The bits in red are the parity bits.

- 1 or 2 stop bits.

- The START bit signals to the receiver that a new character is coming.
- The next 5 to 8 bits represent the character.
- If a parity bit is used, it would be placed after all the data bits.
- The next one or two bits always in the mark (logic high, i.e. "1") condition and are called the stop bits. They signal to the receiver that the character is completed.
- Since the START bit is logic low (0), and the stop bit is logic high (1) there are always at least two guaranteed signal changes between characters.

14.5 ASCII format

ASCII stands for American Standard Code for Information Interchange.

	MSB									
	HEX	0	1	2	3	4	5	6	7	
HEX	BIN	000	001	010	011	100	101	110	111	
0	0000	(NUL)	(DLE)	Space	0	@	P	'	p	
1	0001	(SOH)	(DC1)	!	1	A	Q	a	q	
2	0010	(STX)	(DC2)	"	2	B	R	b	r	
3	0011	(ETX)	(DC3)	#	3	C	S	c	s

F	1111	(SI)	(US)	/	?	O	_	o	DEL	

14.6 Baud rate (data transmission speed)

- Baud rate is the rate of data transmission in serial communication.

$$\text{Baud rate} = \frac{1}{\text{Time between transition (Baud)}}$$

Data rate = Rate of data transmission (bits s⁻¹ or Mb s⁻¹)

- In most simple serial communication, baud rate is equal to the data rate.
- Common baud rates include:
 - ▶ 115200
 - ▶ 57600
 - ▶ 19200
 - ▶ 14400
 - ▶ 9600
 - ▶ 4800
 - ▶ 2400
 - ▶ 1200
 - ▶ etc.

14.6.1 Example

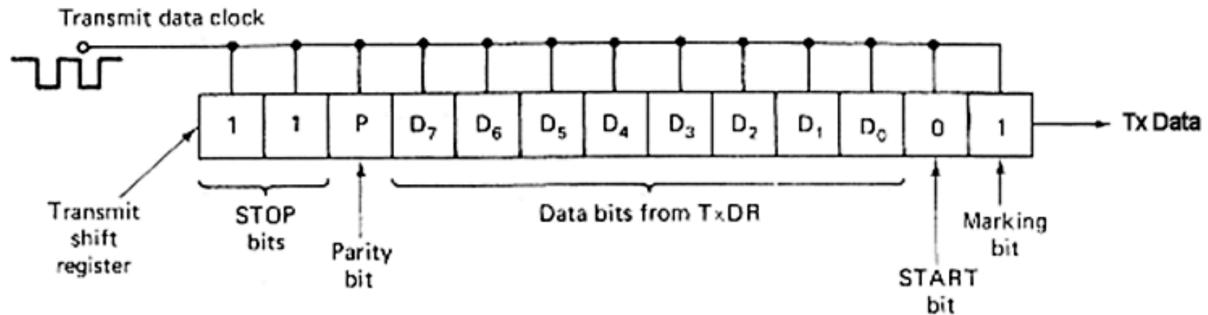

If the baud rate is equal to the data rate of 9600 baud, what is the time duration of 1 bit?

$$\text{Data rate} = 9600 \text{ bits s}^{-1}$$

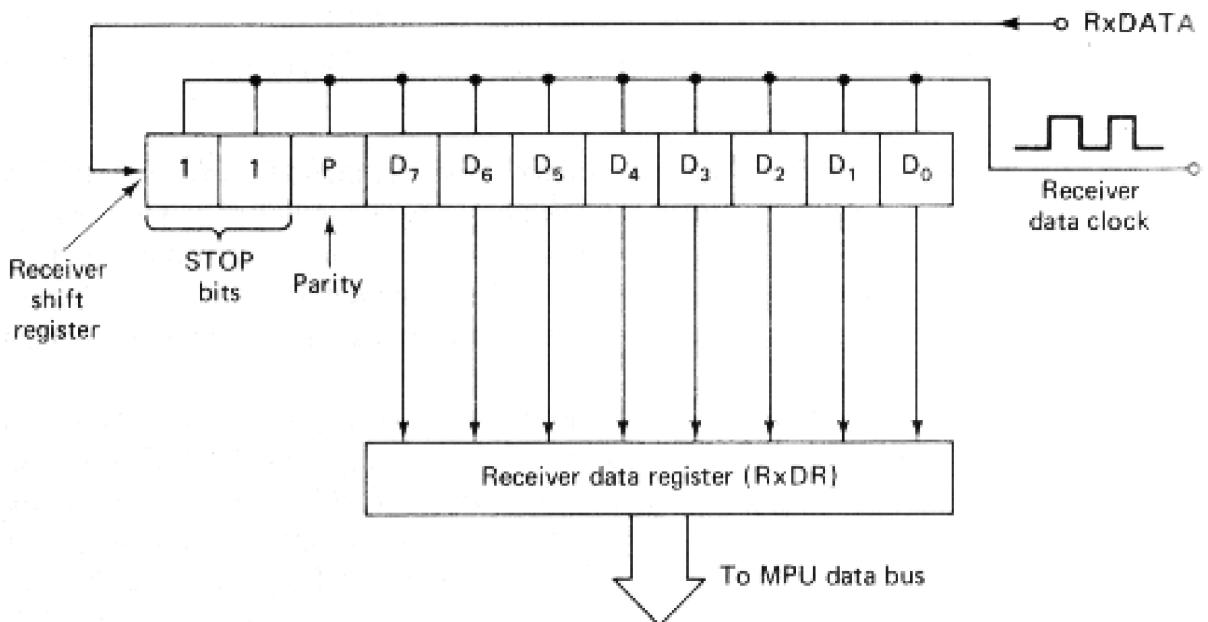

$$\text{Bit time} = \frac{1}{9600} = 104.17 \mu\text{s}$$

14.7 UART data transmission

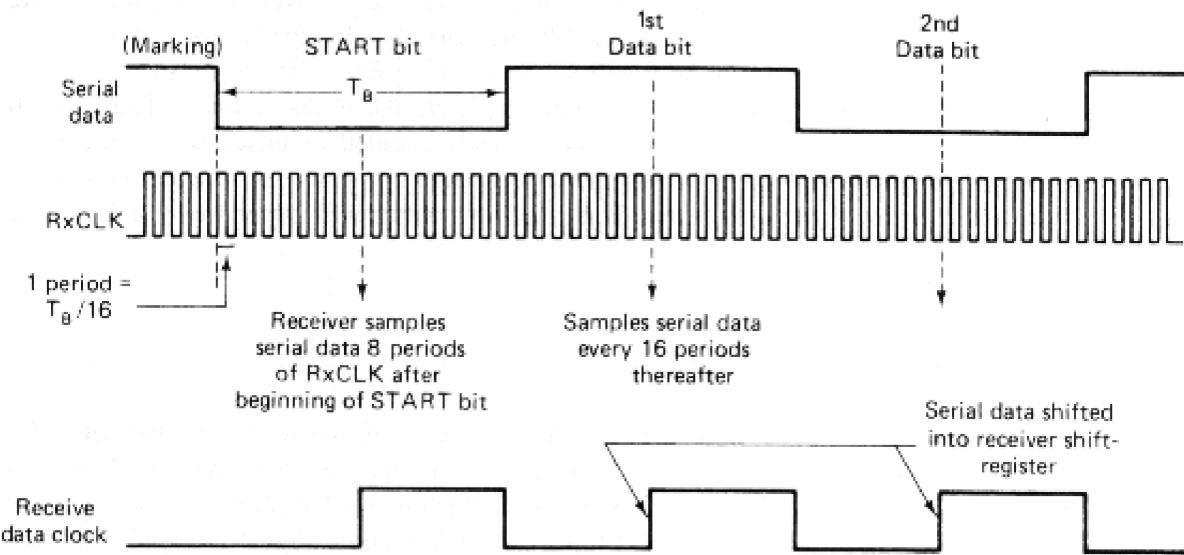

- To transmit a data word from the MCU to a serial output device:
 - MCU sends the data word to the UART's transmitter data register (TxDR).
 - Control logic in the Tx section takes this data word, frames it with a START bit, parity bit, and stop bits, and then places it in the transmit shift register.
 - Contents of this shift register are shifted right at a rate determined by the transmit data clock, where the clock frequency is the baud rate.

- To send a data word from a serial input device to the microcontroller:
 - Serial input device transmit a serial data word to the UART's receiver section through the RxDATA input.
 - Upon receiving a START bit on the RxDATA line, the Rx section shifts the remainder bits of the data word into the receiver shift register.
 - The transmission rate is determined by the receiver data clock.
 - When the complete word is in the register, the data portion ($D_7 - D_0$) is transferred in parallel to the RxDR.
 - The microcontroller reads the contents of RxDR like other memory locations.

14.8 Syncing receiver section with serial data

To ensure reliable data transmission, the receiver needs to sample the signal at a rate that is high enough to capture the changes in the signal.

The baud rate determines the frequency of the signal changes, so the sampling rate needs to be a multiple of the baud rate.

Sampling at 16× the baud rate provides several benefits:

1. **Accurate data recovery:** Sampling at 16× ensures that the receiver can accurately detect the start and stop bits, as well as the data bits.
2. **Noise tolerance:** Sampling at a higher rate helps to reduce the impact of noise on the signal, making the transmission more reliable.
3. **Clock recovery:** The 16× sampling rate allows the receiver to recover the clock signal from the transmitter, ensuring proper synchronisation.

While other sampling rates are possible, 16× has become the standard for UART communication due to its balance between accuracy, noise tolerance, and clock recovery.

- External clock of UART is 16 times faster than the baud rate, i.e. 1 period of RxCLK = $\frac{T_B}{16}$
 - For example:

$$\text{Baud rate} = 9600$$

$$\text{RxCLK} = 16 \times 9600 = 153.6 \text{ kHz}$$

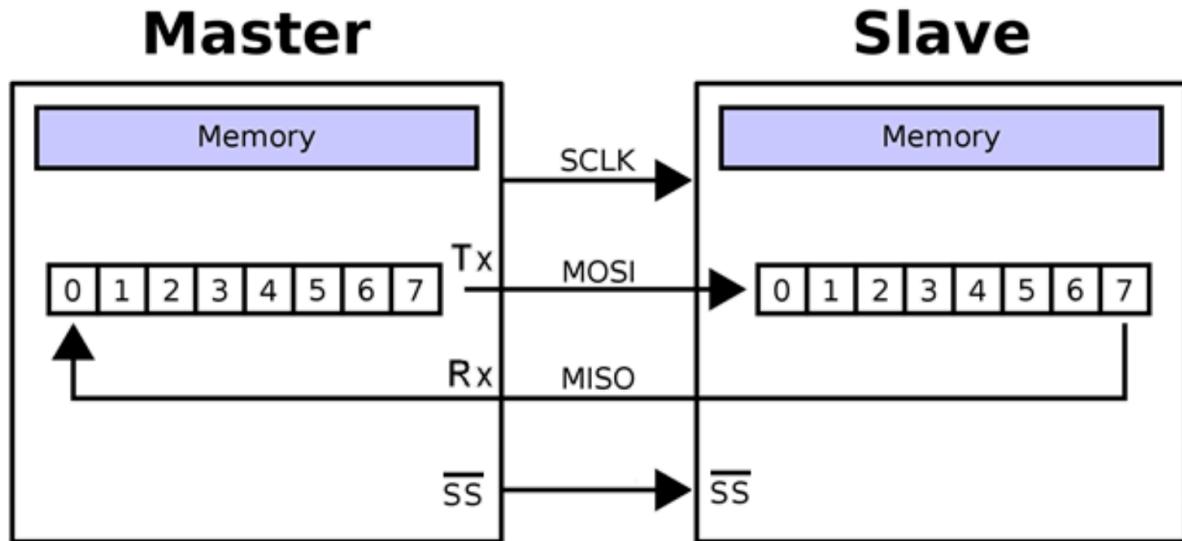

- RxCLK set to divide by 16 (MOD 16) when samples are shifted to the shift register. This makes the frequency of the received data clock be the same as the baud rate.

14.8.1 Syncing procedure

1. After sensing the first negative going transition (falling edge), the receiver waits for 8 cycles of RxCLK, then samples to see if the serial input is still low, to ensure that it is a START bit.
2. Receiver samples the serial data at every 9th cycle of the 16 RxCLK cycles (~1 bit time)
3. Each sample is shifted into the receiver shift register on the rising edge of the receiver's data clock.
4. UART checks if STOP bits are 1s, if not, a **framing error** flag is set.
5. UART checks for parity to be even, if not, a **parity error** flag is set.
6. Data bits are transferred in parallel to the RxDR.
7. Receiver continues to shift data bits into the receiver shift register.
8. This second word will not be transferred into the RxDR until the first word is read by the microcontroller.
9. If the third word arrives before the first word is cleared, it will overwrite the second word. An **overrun error** flag will be set.
10. This can be avoided with the correct baud rate setting.

15 Synchronous serial interface (SSI)

- Another common name for synchronous serial interface is serial peripheral interface (SPI).
- SSI is widely used as a serial interface between an absolute position sensor and a microcontroller.
- SSI uses a clock pulse train from a microcontroller to initiate a gated output form the sensor.
- Operates as master or slave.
- Channels can operate as one master to a single or multiple slaves.
- Communication is always in duplex mode.

- Tx (Master out, Slave in, MOSI) data line is driven by the master and received by the slave.
- Rx (Master in, Slave out, MISO) data line is driven by the slave and received by the master.

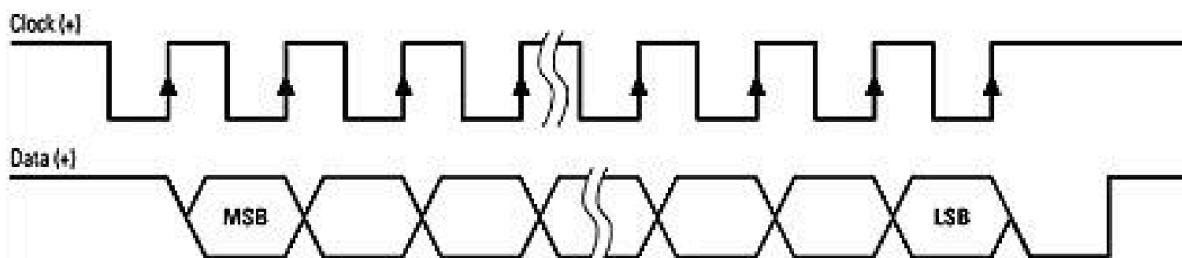

Figure 2: SSI timing diagram

- Transmitting devices uses the edge of one clock to change the output and the receiving device uses other edge to accept the data.
- Classified as synchronous devices as one hardware clock is shared between the devices.

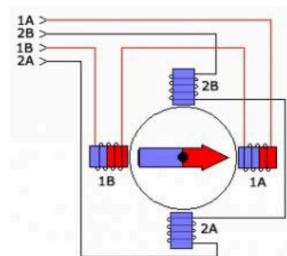

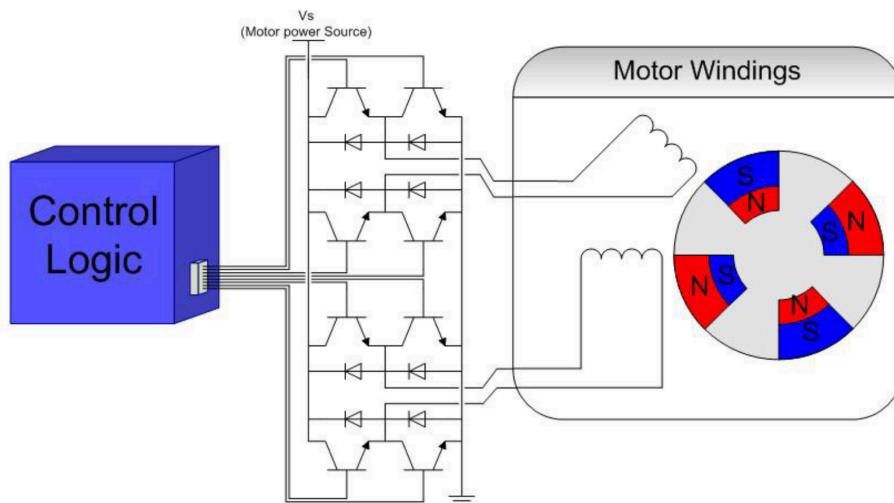

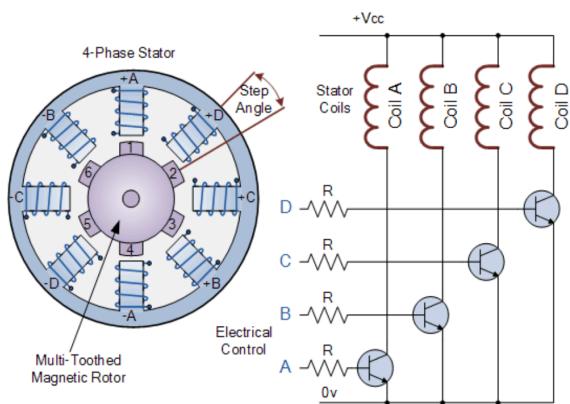

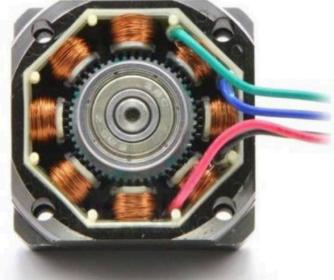

15.1 UART vs SSI

UART	SSI
Asynchronous protocol	Synchronous protocol
Two devices operate at the same frequency (baud rate) but have 2 separate clocks.	Two devices operate with the same clock with one clock frequency.
Two clocks must have frequency within 5% of each other	The master creates the clock and the slave uses the clock to latch the data, either for input or output.
Lines: Tx, Rx and Gnd	Lines: Tx, Rx, Clk, Fss (optional)

16 Stepper motors

16.1 Working principle

- The rotating body is called the rotor.
- The outer body is called the stator.
- The rotor is made of a permanent magnet.
- The stator has a set of electromagnets.
- When one pair of electromagnets is on, the rotator will make one step motion order to align with the stator's magnetic field.
- By changing the sequence of energising the stator's electromagnet, we can get the rotator to make stepwise motions.

16.2 Advantages

- Easy to control as each pulse produces a respective step angle of the motor.
- Mounting space is small.
- Stepper motor will hold their position when stationary, which requires power.
- The stepper motor driver board is cheaper compared to other drivers like PWM or servo motor driver boards.

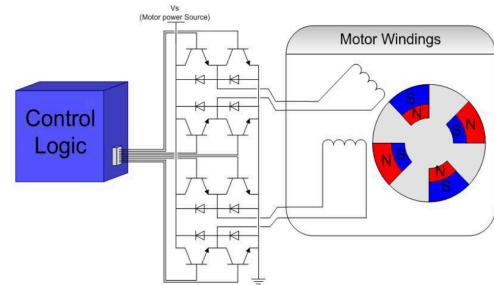

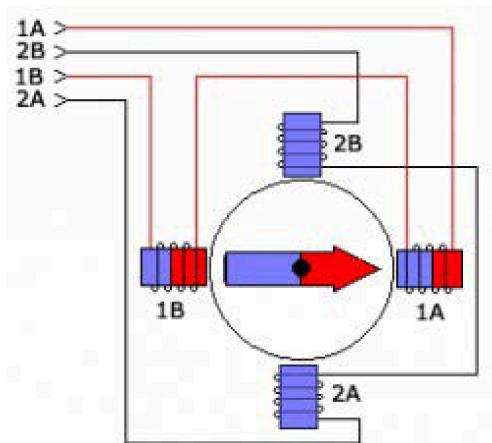

16.3 Disadvantages

- The design of the driver is not an efficient one.
- It requires a lot of wiring for the application.
- Larger stepper motors require heat sinks to dissipate heat from the stepper motor when they are stationary.

16.4 Applications

- Printers (2D and 3D)
- Robotic arms
- Autonomous vehicles

16.5 Output control

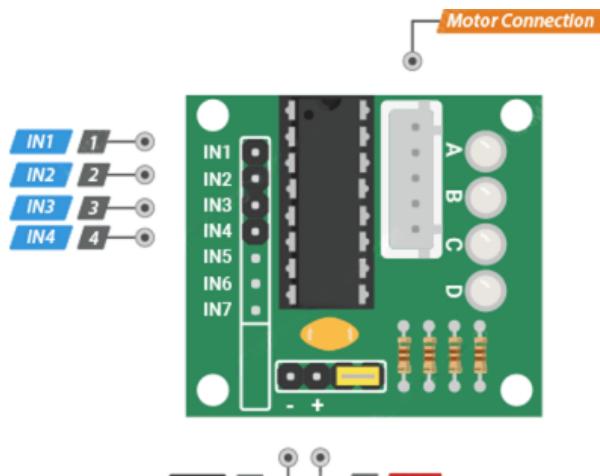

Phase 1:

1. 1A: Powered, 1B: Depowered
2. 1A: Depowered, 1B: Powered

Phase 2:

1. 2A: Powered, 2B: Depowered
2. 2A: Depowered, 2B: Powered

16.5.1 Example

ULN2003 Driver Pinout

Figure 3: ULN2003 stepper motor driver board

- IN1 - IN4 pins are used to drive the motor. Connect them to a digital output pins on the TM4C123G Launchpad (e.g. PC4, PC5, PC6, PC7).
- GND is a common ground pin.
- VDD pin supplies power for the motor. Connect it to an external 5 V power supply. Do not use the 5 V power from the TM4C123G Launchpad.
- The motor connector is where the stepper motor plus into. The connector is keyed, so it only goes one way.

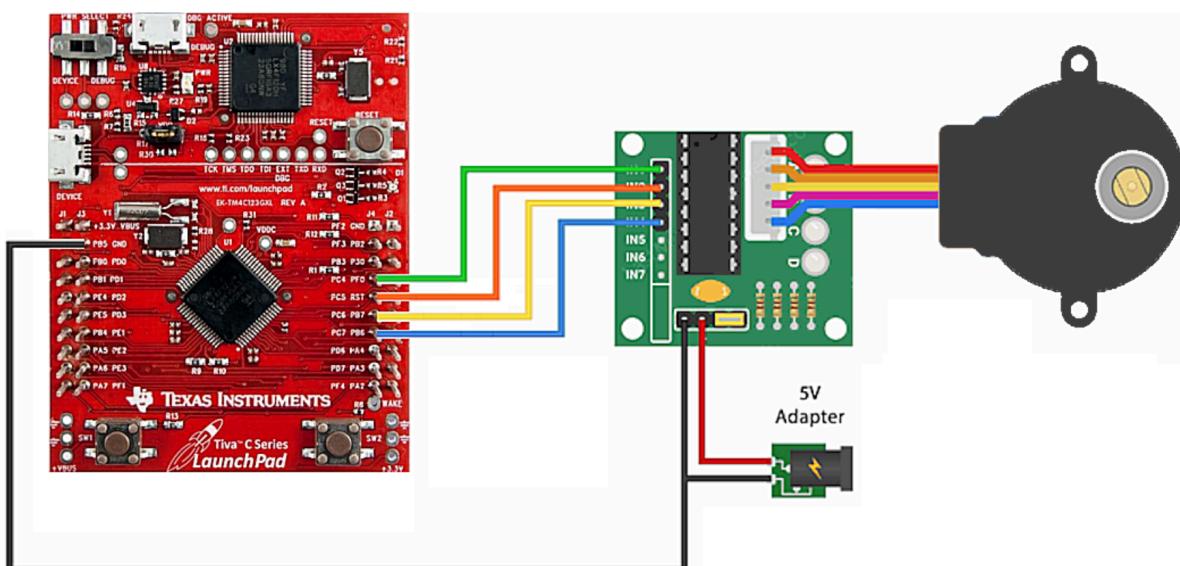

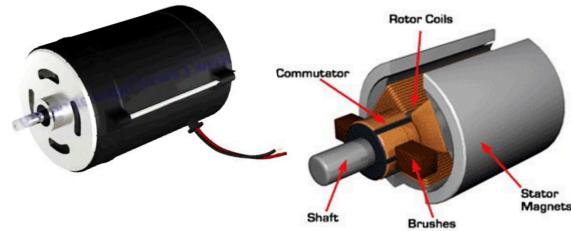

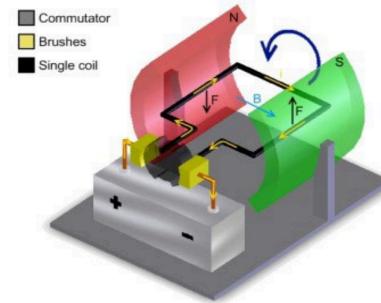

Figure 4: TM4C123G, ULN2003 stepper driver, and stepper motor connection diagram.

17 Brushed DC motors

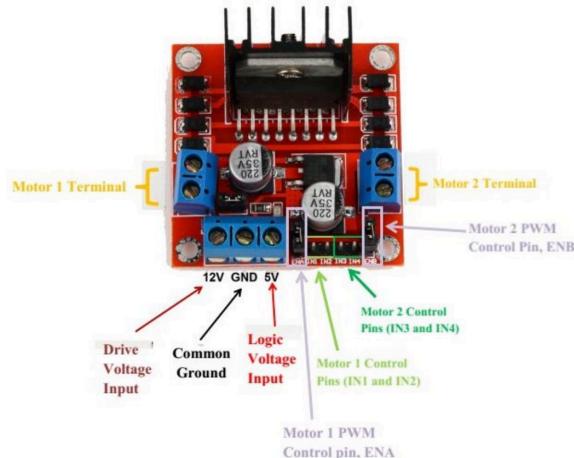

17.1 Working principle

- The stator is made of a permanent magnet.
- The rotor has a set of rectangular coils.
- When the rectangular coils are parallel to the magnetic field, current will pass through the coils. Also, the edges perpendicular to the magnetic flux will produce magnetic forces, which make the coils rotate in one direction.
- The motion of the rotor will bring another rectangular coil into being parallel with the magnetic field. The process repeats.

17.2 L289N H-bridge motor driver

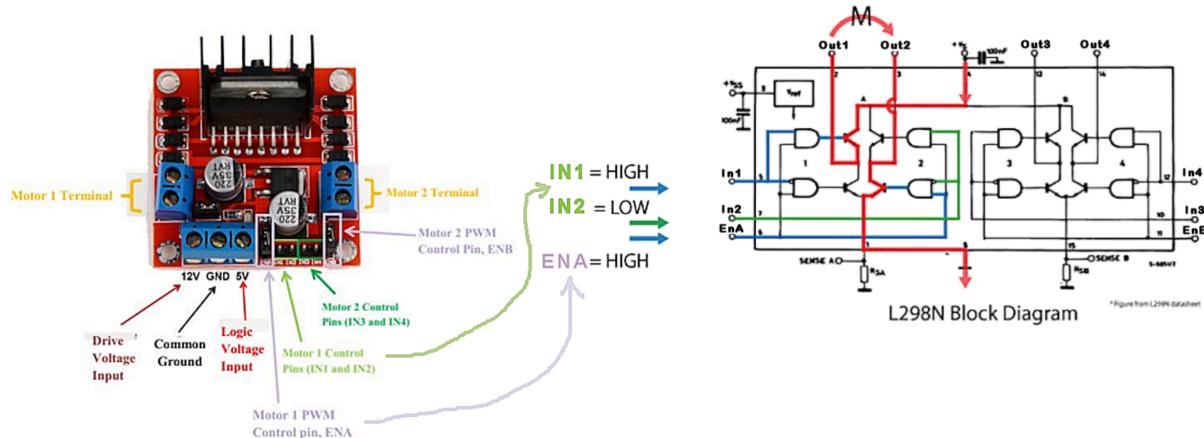

- There are two terminals with two connections. Hence, the driver can support 2 DC motors at a time.
- IN1 and IN2 are the direction control pins for the motor 1, which controls the first internal H-bridge within the driver.
- IN3 and IN4 are the direction control pins for the motor 2, which controls the second internal H-bridge within the driver.
- ENA and ENB controls motor 1 and motor 2 respectively. Keeping these pins on logical high will let the DC motors rotate. Pulling these pins to a low state will turn off the motors.
- By removing jumpers, we can apply a PWM signal to each pin instead of just an on/off signal.

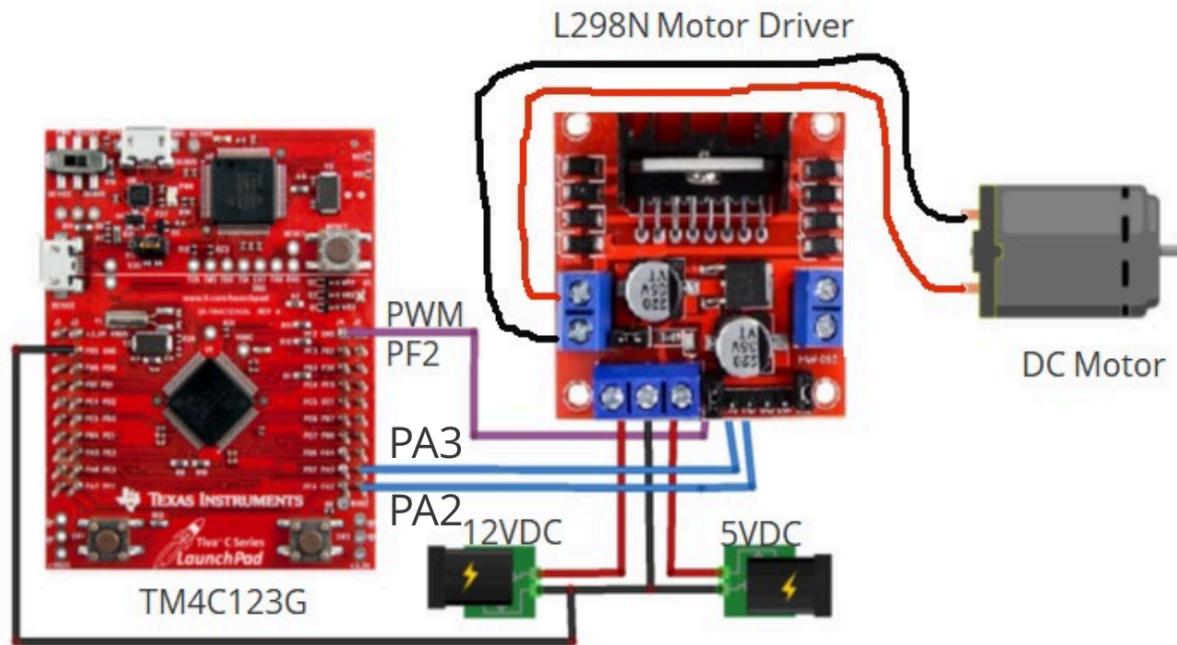

17.2.1 Output control

17.2.1.1 PWM logic control

- Clockwise (CW) rotation:
 - ▶ IN1 high.
 - ▶ IN2 low.
 - ▶ ENA supplies PWM pulses.
- Counter-clockwise (CCW) rotation:
 - ▶ IN1 low.
 - ▶ IN2 high.
 - ▶ ENA supplies PWM pulses.

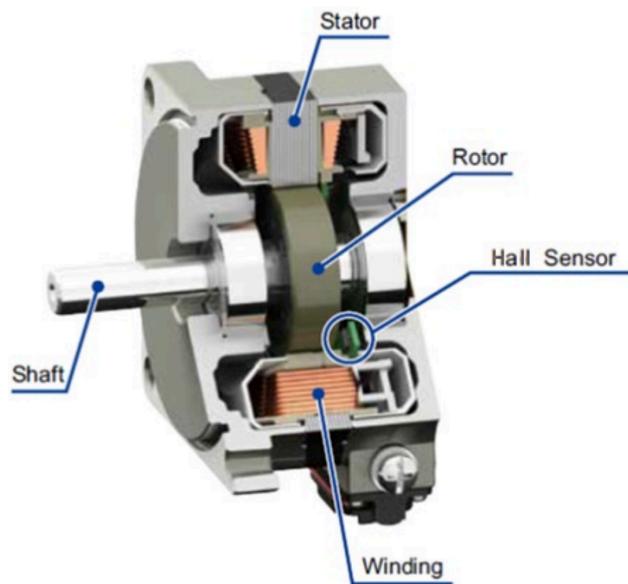

17.2.1.2 PWM power control

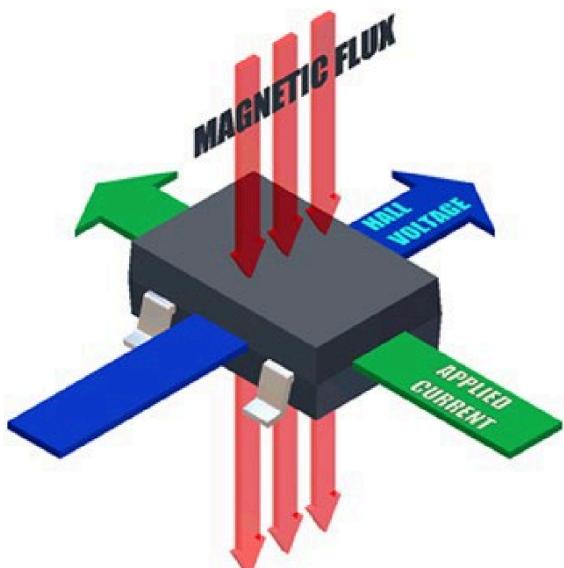

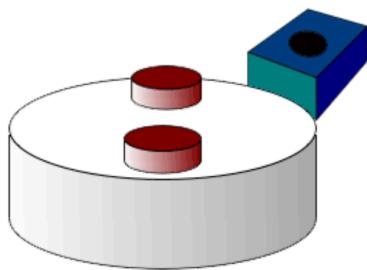

- To drive a DC motor using a TM4C123G with a L298N motor driver, three signals to the L298N motor driver from the TM4C123G are required.
- Two signals to control the direction (e.g. GPIO PA2 and PA3) to provide active high/low to the L298N and one PWM signal (PF2).

18 Brushless DC motors

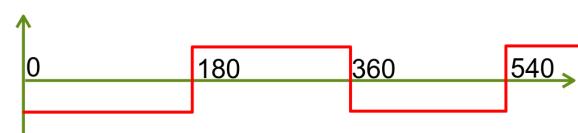

18.1 Hall effect sensor

When a magnetic flux passes through the sensor, a voltage is produced as output.

Hall Effect Sensor

18.2 Working principle

- The rotor is made of a permanent magnet.
- The stator has a set of electromagnets.
- The stator's electromagnets are sequentially excited to create a rotating magnetic field.
- The stator's rotating magnetic field will cause the rotator to follow the rotation.
- The hall sensors are employed to provide the position feedback so as to synchronise the commutation of excitations.

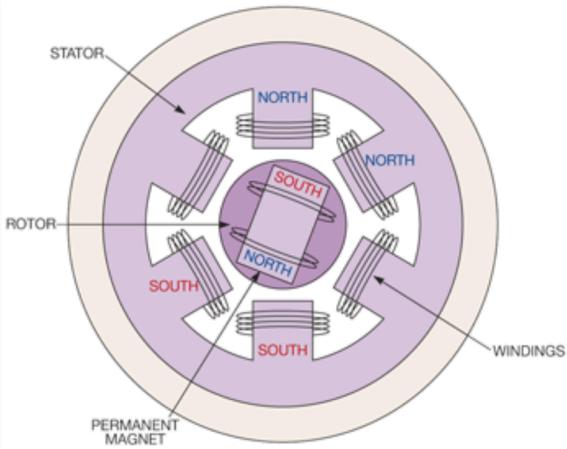

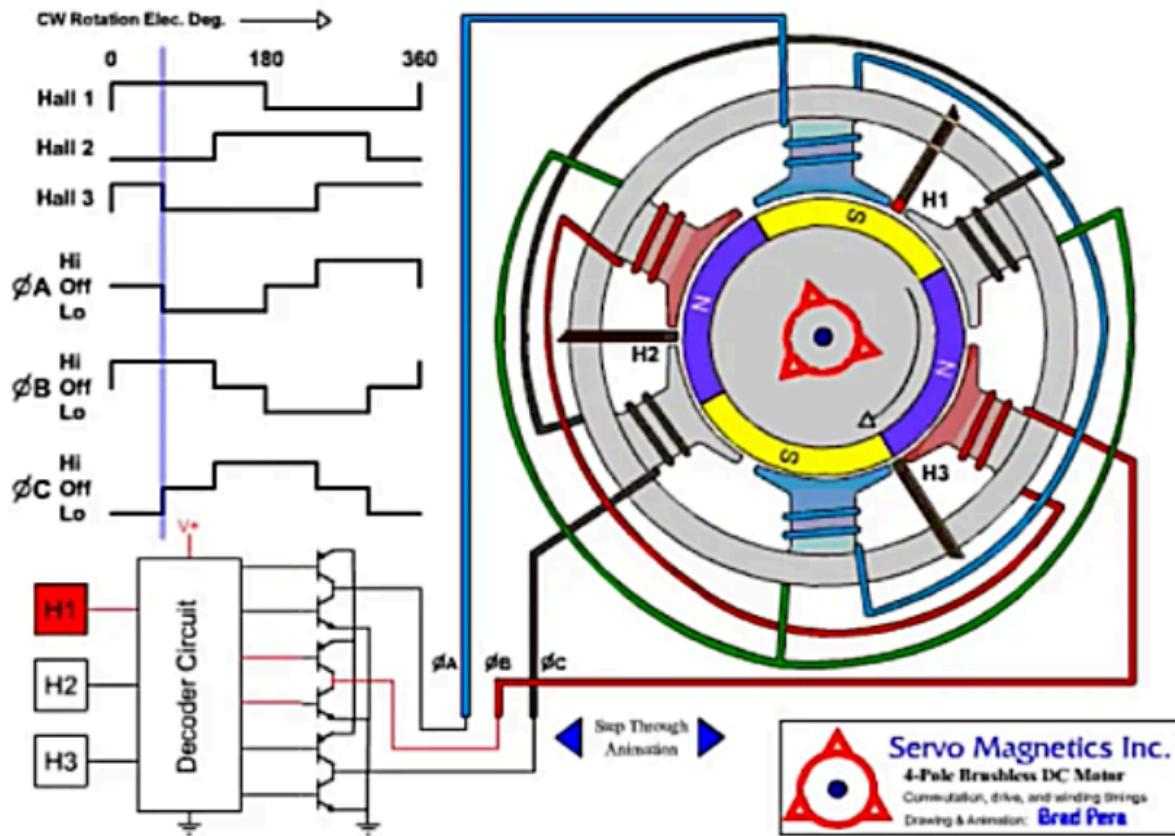

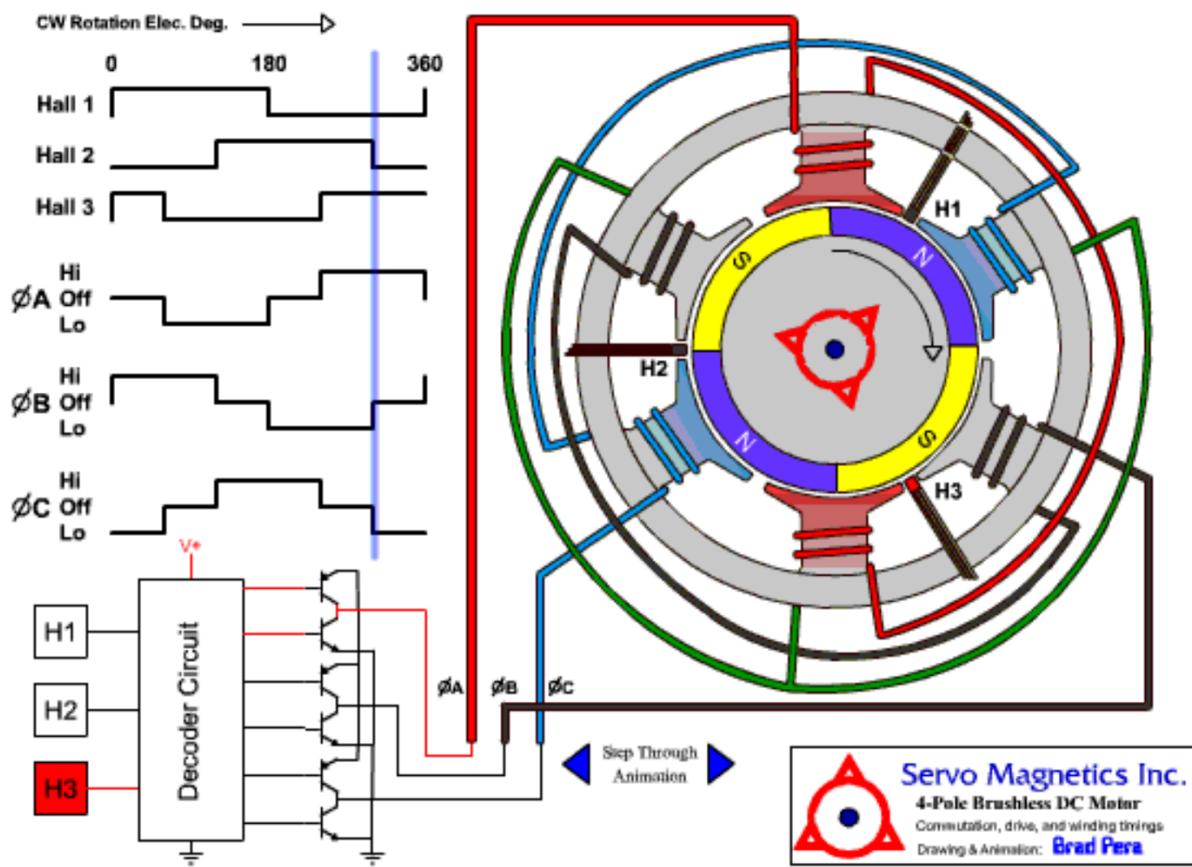

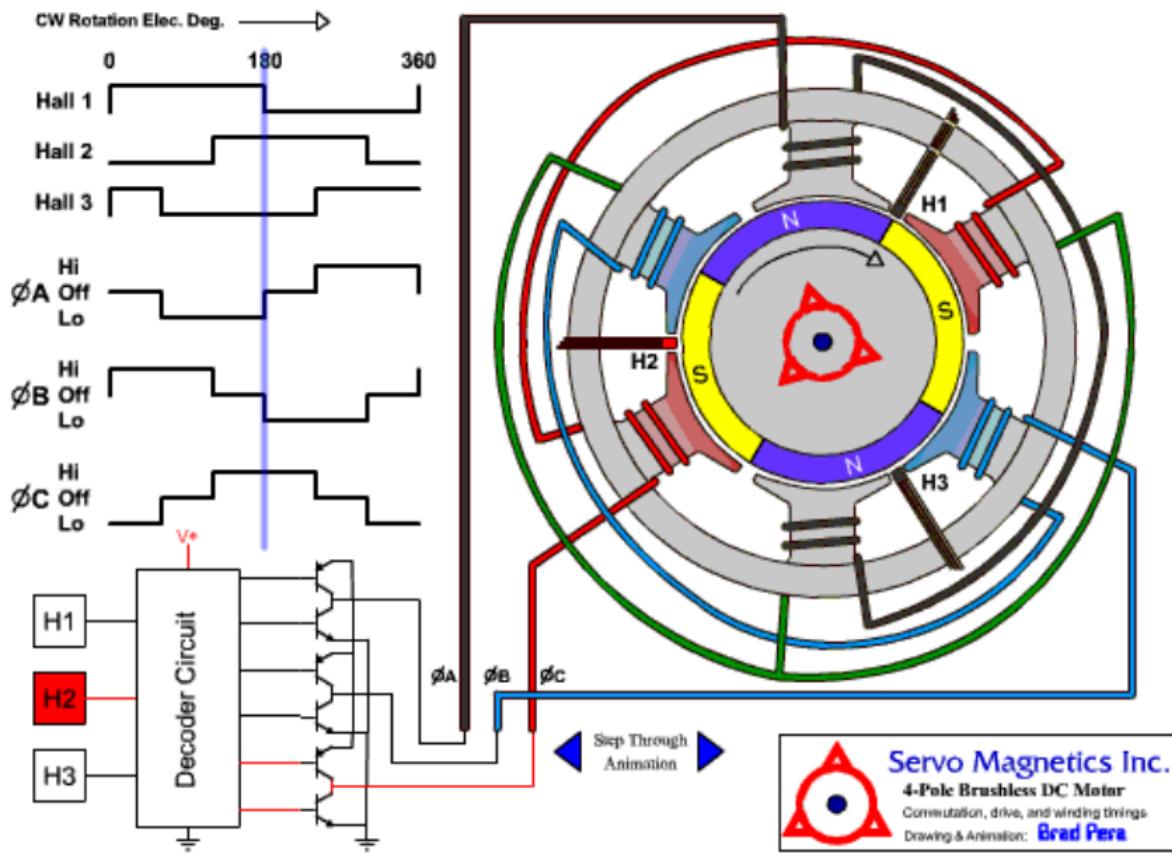

Figure 5: Brushless DC motors have a rotor with a permanent magnet containing a north and south poles. The stator comprises multiple electromagnets.

18.3 Sequence

18.4 Advantages

Brushless DC motors are more efficient as its velocity is determined by the frequency at which the current is supplied, not the voltage.

1. As brushes are absent, the mechanical energy loss due to friction is less, which enhances efficiency.
2. Brushless DC motors can operate at high-speeds under any condition.
3. There is no sparking and there is much less noise during operation.
4. More electromagnets could be used on the stator for more precise control.
5. Brushless DC motors accelerate and decelerate easily as they have low rotor inertia.
6. They are also high performance motors that provide a large torque per cubic inch over a large speed range.
7. Brushless DC motors do not have brushes, which make them more reliable, last longer, and require very little maintenance.
8. There are no ionising sparks from the commutator, and electromagnetic interference is also reduced.
9. Such motors could be cooled by conduction, and no air flow is required to cool the insides of the motor.

18.5 Disadvantages

1. Brushless DC motors cost more than a brushed DC motor.
2. The power of the motor is limited, as too much heat weakens the magnets and may damage the insulation of the winding.

19 TM4C123GH6PM General Purpose Input/Output (GPIO)

19.1 Key features

- Six ports: ports A, B, C, D, E and F.
- Ports A to F are accessed through Advanced Peripheral Bus (APB).
- 43 programmable pins: 7:0 PA - PD, 5:0 PE, 4:0 PF
- Pins configured as digital inputs are Schmitt-triggered.
- Programmable control of GPIO's interrupts.
- Programmable control of GPIO's pad configuration.

19.2 Process of operating GPIO

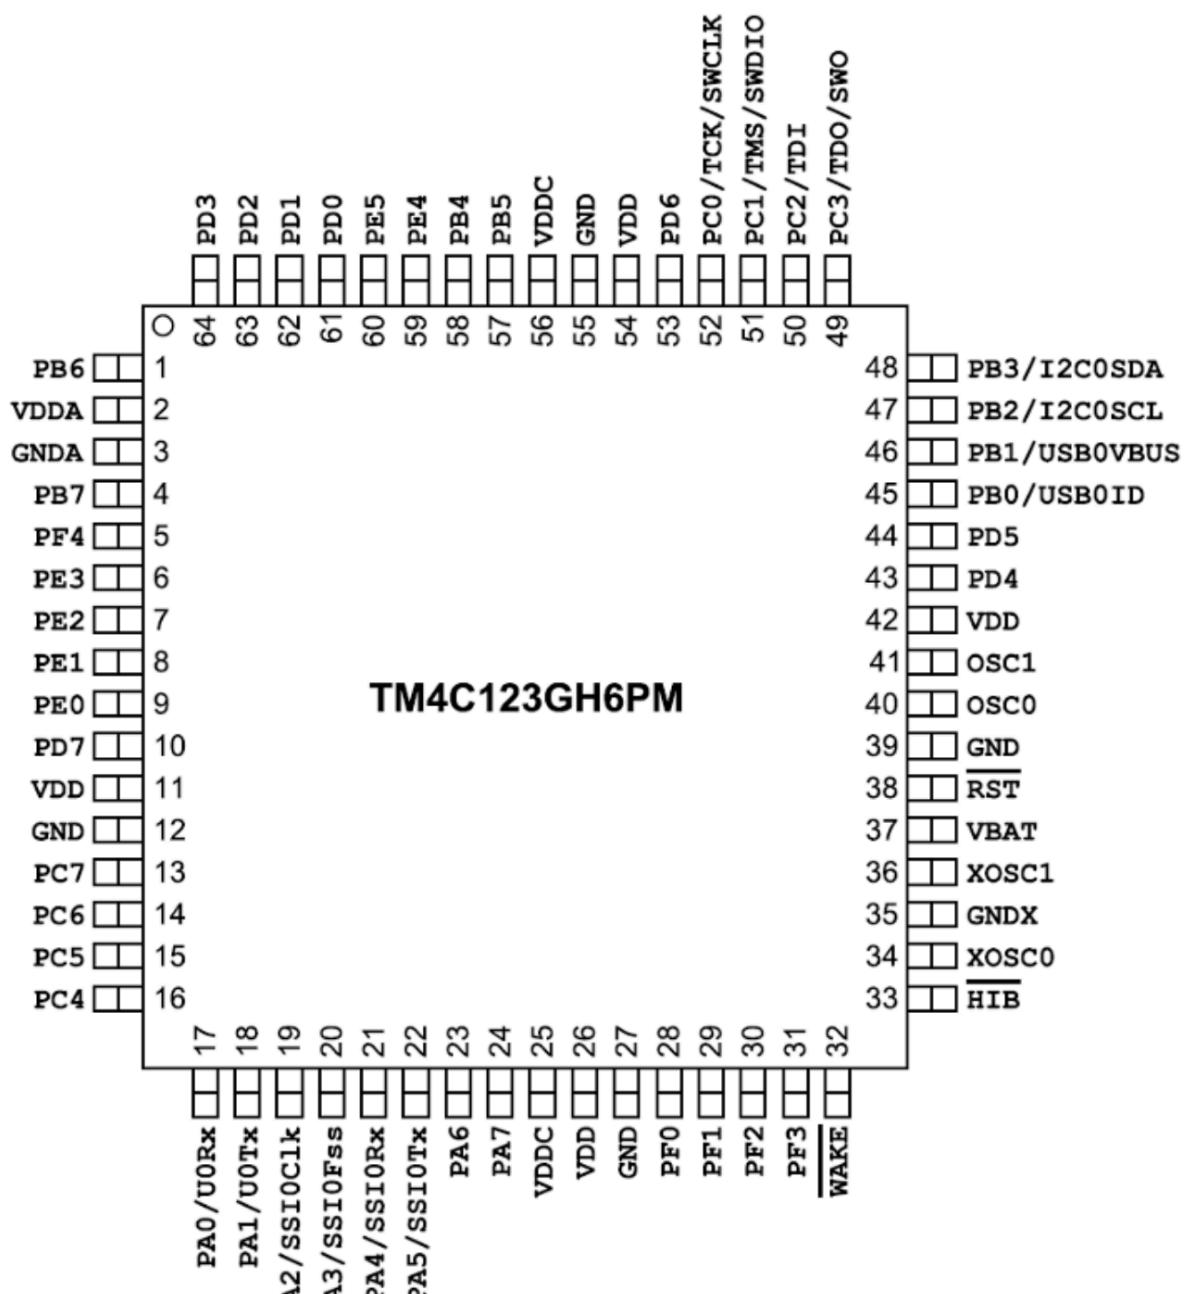

Control registers are used to:

- Configure input
- Configure internal processes

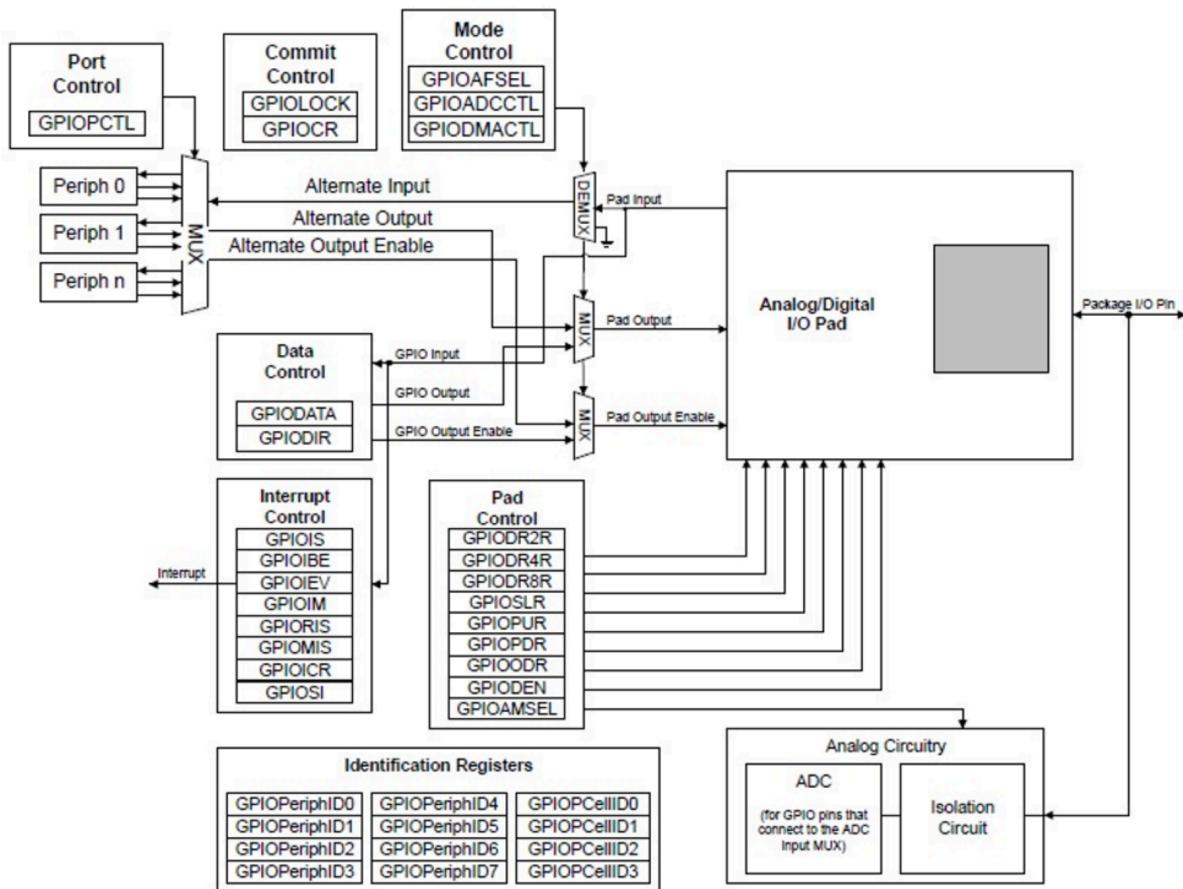

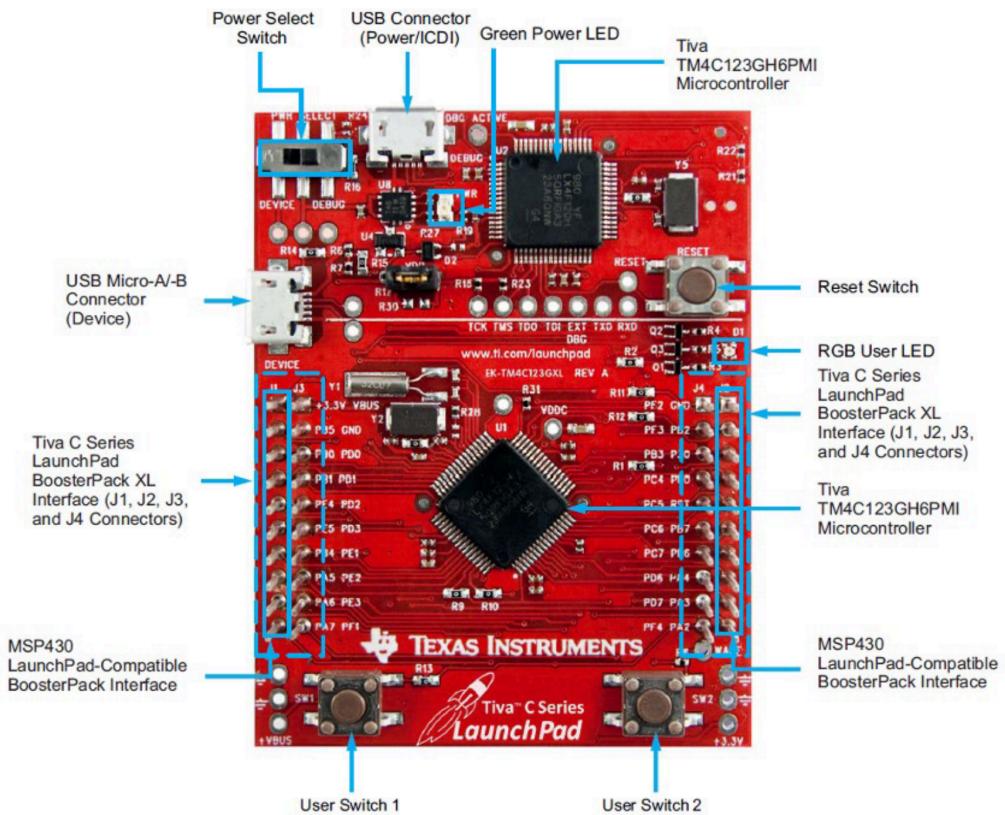

Status registers are used to:

- Configure output
- Run GPIO

1	The analog function of the pin is enabled, the isolation is disabled, and the pin is capable of analog functions.									

19.7.19 GPIO Data (GPIODATA)

- GPIO Port A (APB) base: 0x4000.4000
- GPIO Port A (AHB) base: 0x4005.8000
- GPIO Port B (APB) base: 0x4000.5000
- GPIO Port B (AHB) base: 0x4005.9000
- GPIO Port C (APB) base: 0x4000.6000
- GPIO Port C (AHB) base: 0x4005.A000
- GPIO Port D (APB) base: 0x4000.7000
- GPIO Port D (AHB) base: 0x4005.B000
- GPIO Port E (APB) base: 0x4002.4000
- GPIO Port E (AHB) base: 0x4005.C000
- GPIO Port F (APB) base: 0x4002.5000
- GPIO Port F (AHB) base: 0x4005.D000
- Offset 0x000
- Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:0	DATA	RW	0x00	<p>GPIO Data</p> <p>This register is virtually mapped to 256 locations in the address space. To facilitate the reading and writing of data to these registers by independent drivers, the data read from and written to the registers are masked by the eight address lines [9:2]. Reads from this register return its current state. Writes to this register only affect bits that are not masked by ADDR[9:2] and are configured as outputs.</p>

Figure 10-3. GPIODATA Write Example

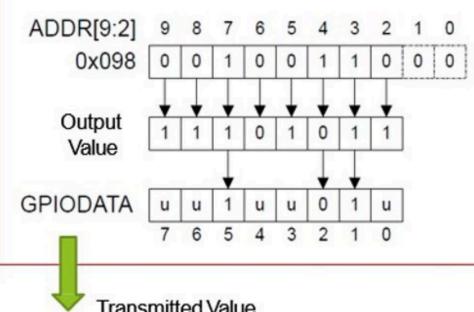

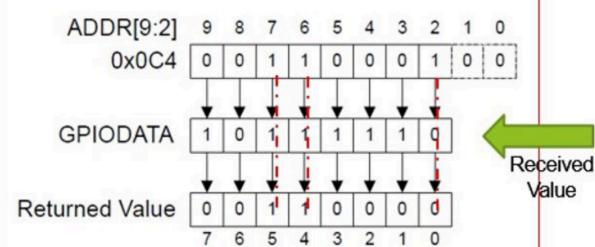

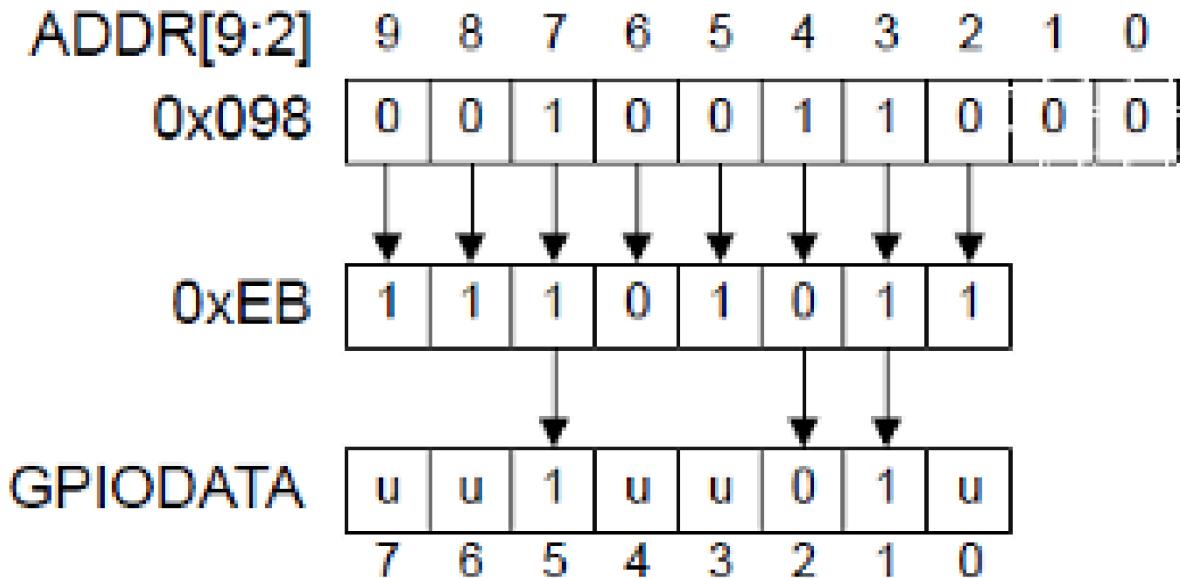

Figure 10-4. GPIODATA Read Example

19.7.19.1 GPIO write example

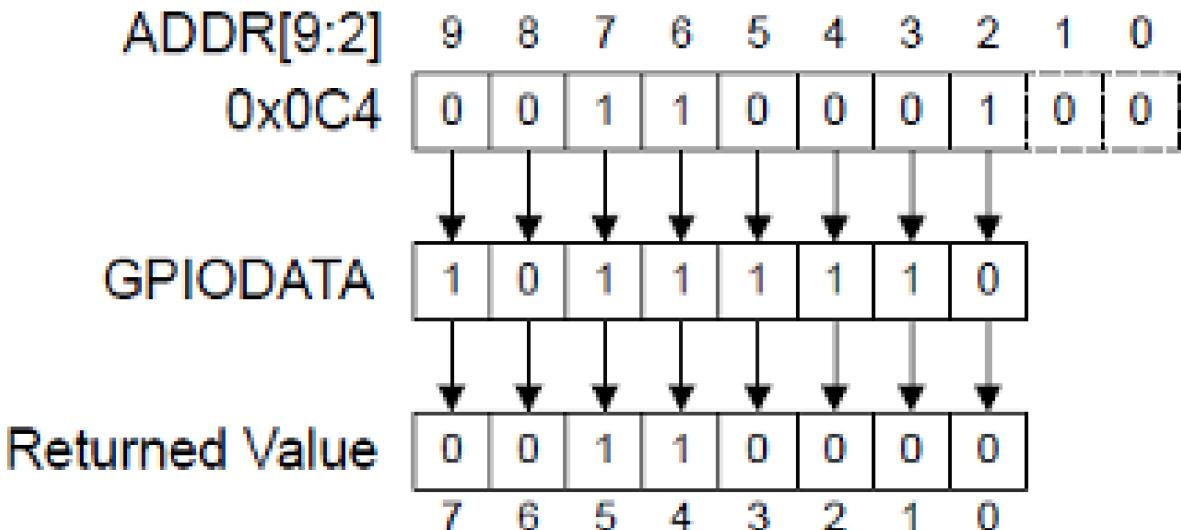

During a write, if the address bit associated with that data bit is set, the value of the **GPIODATA** (page 153) register is altered. If the address bit is cleared, the data bit is left unchanged.

For example, writing a value of 0xEB to the address **GPIODATA** (page 153) + 0x098 has the results shown below, where u indicates that data which are not changed by the write operation. The example below shows **GPIODATA** (page 153) bits 5, 2, and 1 being written.

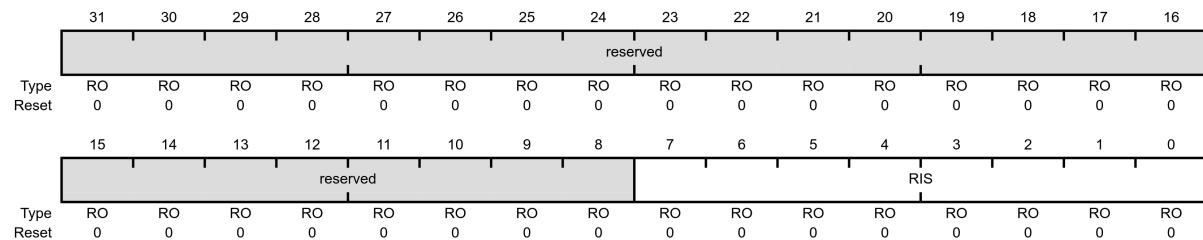

19.7.19.2 GPIO read example

During a read, if the address bit associated with the data bit is set, the value is read. If the address bit associated with the data bit is cleared, the data bit is read as a zero, regardless of its actual value. For example, reading address **GPIODATA** (page 153) + 0x0C4 yields the value shown below. The example below shows how to read **GPIODATA** (page 153) bits 5, 4, and 0.

19.7.20 GPIO Raw Interrupt Status (GPIORIS)

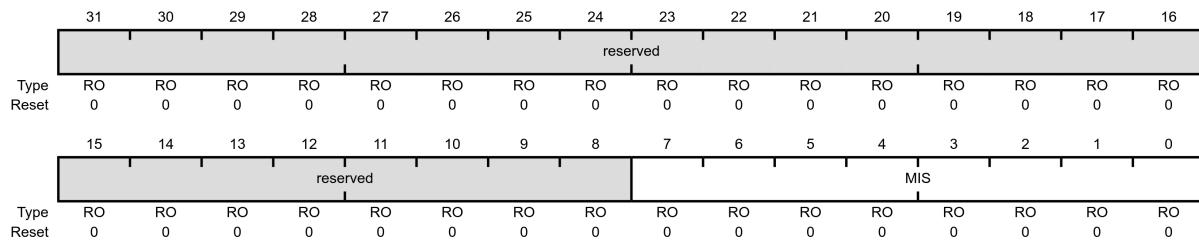

- GPIO Port A (APB) base: 0x4000.4000
- GPIO Port A (AHB) base: 0x4005.8000

0	The corresponding pin is not used to trigger the ADC.									
1	The corresponding pin is used to trigger the ADC.									

19.8 Initialisation

1. Enable the clock for the port using the **RCGCGPIO** (page 133) register.
2. Enable or disable analogue functionality using the **GPIOAMSEL** (page 152) register.
3. Configure the pins as GPIO or non-GPIO using the **GPIOPCTL** (page 158) register.
4. Set the pin's direction, like input or output using the **GPIODIR** (page 136) register.
5. Enable (1) or disable (0) the alternate function using the **GPIOAFSEL** (page 148) register.
6. Enable (1) or disable (0) pull-up resistors if needed using the **GPIOPUR** (page 145) register.
7. Enable (1) or disable (0) the digital ports using the **GPIODEN** (page 135) register.

Port: --76 5432 10--

Binary: 0000 0000 0000

20 TM4C123GH6PM Cortex M4 analogue to digital converter (ADC)

20.1 Functions

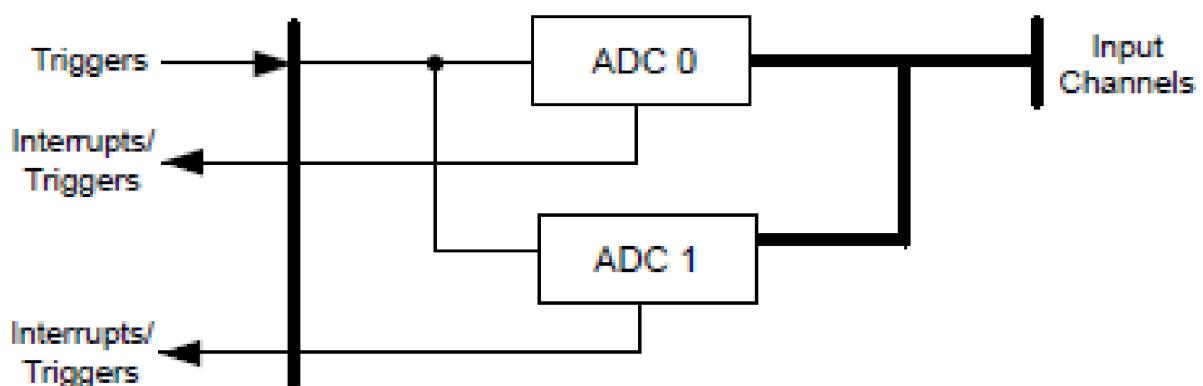

- The TM4C123GH6PM has two ADC modules sharing 12 input channels each with 12-bit resolution, plus an internal temperature sensor.
- Each ADC module has 4 programmable sample sequencers allowing the sampling of multiple analogue input sources.
- Each sample sequencer provides fully programmable input source, trigger events, interrupt generation, and sequencer priority. Conversion values can be diverted to a digital comparator module. Each ADC module provides 8 digital comparators.
- Each digital comparator evaluates the ADC conversion value against its two user-defined values to determine the operation range of the signal. The trigger source for ADC0 and ADC1 may be independent of the two ADC modules may operate from the same trigger source and operate on the same or different inputs.
- A phase shifter can delay the start of the sampling by a specified phase angle.

20.2 Main features

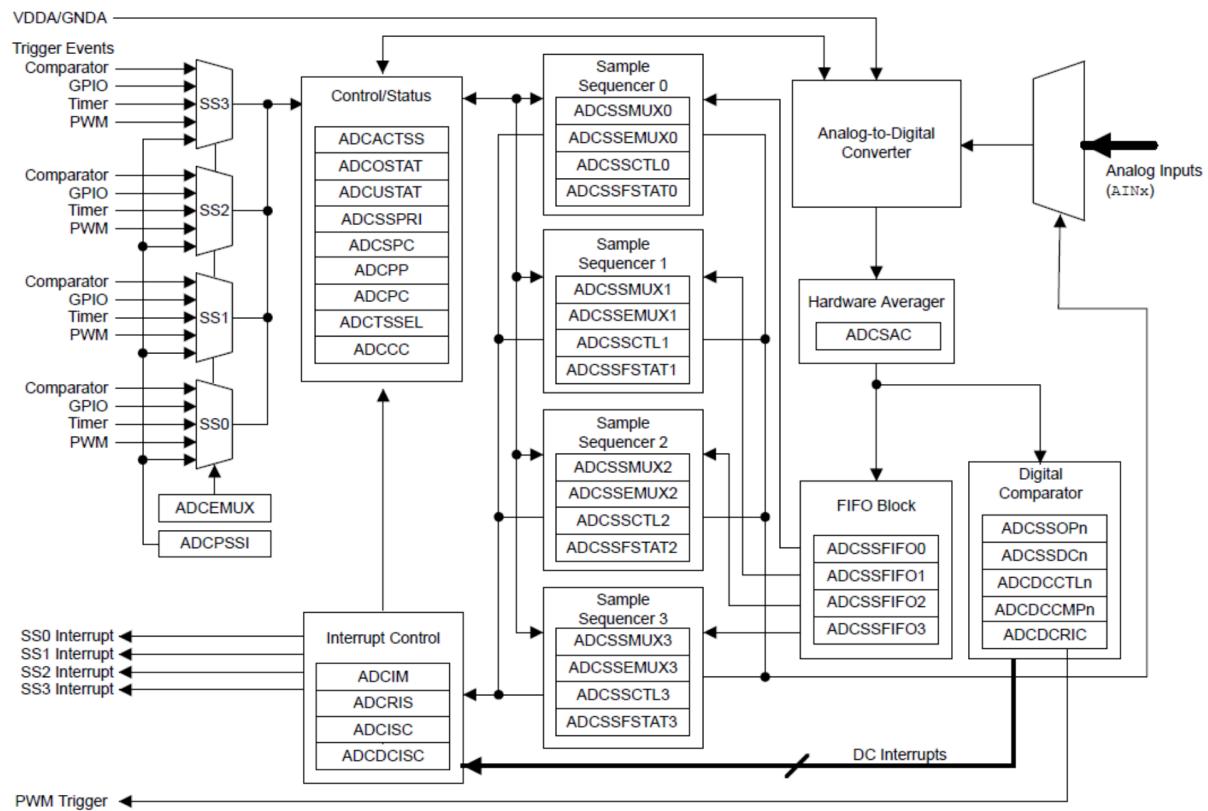

The TM4C123GH6PM provides two ADC modules each having:

- 12 shared analogue input channels
- 12-bit precision analogue to digital converter
- On-chip internal temperature sensor
- Maximum sample rate of up to one million samples per second
- Four programmable sample conversion sequencers from 1 to 8 entries long, with corresponding conversion result FIFOs.
- Flexible trigger control, like controllers, timers, GPIO, analogue comparators, PWM.
- Hardware averaging of up to 64 samples.
- 8 digital comparators
- ADC clock runs at 16 MHz

20.3 Implementation of 2 ADC blocks

20.4 ADC module block diagram

20.5 ADC signal pin names

- The AIN x signals are analogue functions for some GPIO signals.
- Pin or mux assignment is configured by clearing the DEN bit in **GPIODEN** (page 135) and setting the **GPIOAMSEL** (page 152) register.

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
AIN0	6	PE3	I	Analog	Analog-to-digital converter input 0.
AIN1	7	PE2	I	Analog	Analog-to-digital converter input 1.
AIN2	8	PE1	I	Analog	Analog-to-digital converter input 2.
AIN3	9	PE0	I	Analog	Analog-to-digital converter input 3.
AIN4	64	PD3	I	Analog	Analog-to-digital converter input 4.
AIN5	63	PD2	I	Analog	Analog-to-digital converter input 5.
AIN6	62	PD1	I	Analog	Analog-to-digital converter input 6.
AIN7	61	PD0	I	Analog	Analog-to-digital converter input 7.
AIN8	60	PE5	I	Analog	Analog-to-digital converter input 8.
AIN9	59	PE4	I	Analog	Analog-to-digital converter input 9.
AIN10	58	PB4	I	Analog	Analog-to-digital converter input 10.
AIN11	57	PB5	I	Analog	Analog-to-digital converter input 11.

20.8 Functional description

- The TM4C123GH6PM ADC collects sample data by using a programmable sequence-based approach.
- Each sample sequence is a fully programmed series of consecutive (back-to-back) samples, allowing the ADC to collect data from multiple input sources without having to be re-configured or serviced by the processor.
- The programming of each sample in the sample sequence includes parameters such as the input source and mode (differential versus single-ended input), interrupt generation on sample completion, and the indicator for the last sample in the sequence.
- The sampling control and data capture is handled by the sample sequencers.
- For a given sample sequence, each sample is defined by bit fields in the ADC Sample Sequence Input Multiplexer Select (ADCSSMUXn) ([page 175](#)) and ADC Sample Sequence Control (ADCSSCTLn) ([page 183](#)) registers.

20.9 Registers

20.9.1 ADC Peripheral Properties (ADCPP)

- ADC0 base: 0x4003.8000
- ADC1 base: 0x4003.9000
- Offset 0xFC0
- Type RO, reset 0x00B0.20C7

Type	RW	RW	RW	RW												
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:28	MUX7	RW	0x0	8th Sample Input Select The MUX7 field is used during the eighth sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion. The value set here indicates the corresponding pin, for example, a value of 0x1 indicates the input is AIN1.
27:24	MUX6	RW	0x0	7th Sample Input Select The MUX6 field is used during the seventh sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
23:20	MUX5	RW	0x0	6th Sample Input Select The MUX5 field is used during the sixth sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
19:16	MUX4	RW	0x0	5th Sample Input Select The MUX4 field is used during the fifth sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
15:12	MUX3	RW	0x0	4th Sample Input Select The MUX3 field is used during the fourth sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.
11:8	MUX2	RW	0x0	3rd Sample Input Select The MUX2 field is used during the third sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.

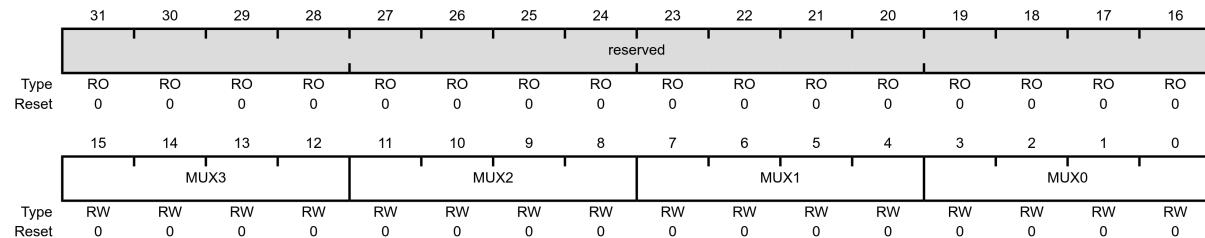

Bit/Field	Name	Type	Reset	Description
7:4	MUX1	RW	0x0	<p>2nd Sample Input Select</p> <p>The MUX1 field is used during the second sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.</p>
3:0	MUX0	RW	0x0	<p>1st Sample Input Select</p> <p>The MUX0 field is used during the first sample of a sequence executed with the sample sequencer. It specifies which of the analog inputs is sampled for the analog-to-digital conversion.</p>

20.9.7 ADC Sample Sequence Input Multiplexer Select n (ADCSSMUXn)

- ADC0 base: 0x4003.8000
- ADC1 base: 0x4003.9000
- Offset 0x060
- Type RW, reset 0x0000.0000

Registers:

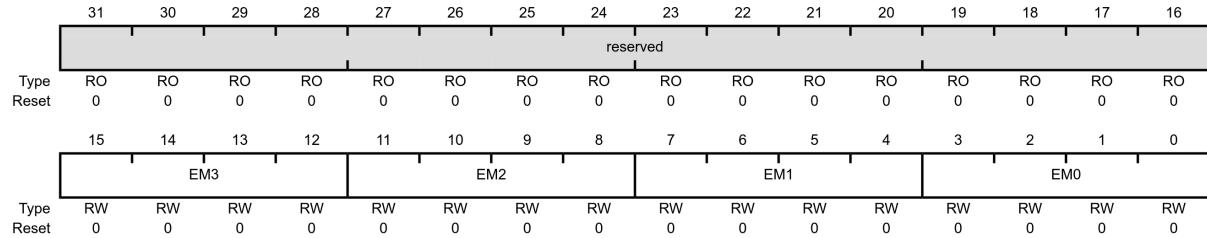

- Register 27: ADC Sample Sequence Input Multiplexer Select 1 (ADCSSMUX1), offset 0x060
- Register 28: ADC Sample Sequence Input Multiplexer Select 2 (ADCSSMUX2), offset 0x080

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:12	MUX3	RW	0x0	4th Sample Input Select
11:8	MUX2	RW	0x0	3rd Sample Input Select
7:4	MUX1	RW	0x0	2nd Sample Input Select
3:0	MUX0	RW	0x0	1st Sample Input Select

20.9.8 ADC Event Multiplexer Select (ADCEMUX)

- ADC0 base: 0x4003.8000
- ADC1 base: 0x4003.9000
- Offset 0x014
- Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:12	EM3	RW	0x0	SS3 Trigger Select This field selects the trigger source for Sample Sequencer 3.
11:8	EM2	RW	0x0	SS2 Trigger Select This field selects the trigger source for Sample Sequencer 2.

20.9.16 ADC Digital Comparator Range n (ADCDCCMPn)

Each comparator has 2 values:

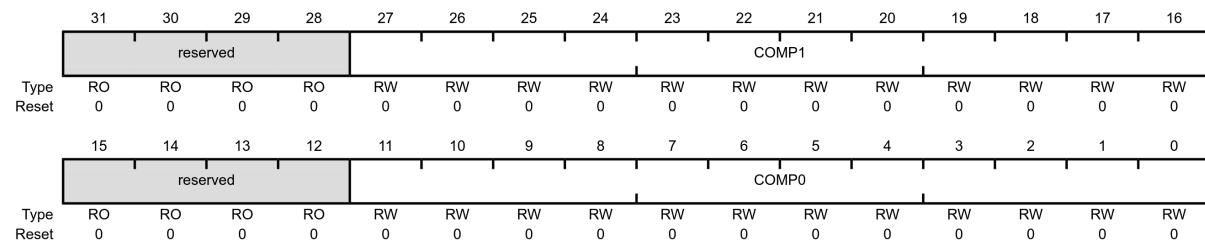

- COMP1: High value
- COMP0: Low value

Documentation:

- ADC0 base: 0x4003.8000
- ADC1 base: 0x4003.9000
- Offset 0xE40
- Type RW, reset 0x0000.0000

Registers:

- Register 48: ADC Digital Comparator Range 0 (ADCDCCMP0), offset 0xE40
- Register 49: ADC Digital Comparator Range 1 (ADCDCCMP1), offset 0xE44
- Register 50: ADC Digital Comparator Range 2 (ADCDCCMP2), offset 0xE48
- Register 51: ADC Digital Comparator Range 3 (ADCDCCMP3), offset 0xE4C
- Register 52: ADC Digital Comparator Range 4 (ADCDCCMP4), offset 0xE50
- Register 53: ADC Digital Comparator Range 5 (ADCDCCMP5), offset 0xE54
- Register 54: ADC Digital Comparator Range 6 (ADCDCCMP6), offset 0xE58
- Register 55: ADC Digital Comparator Range 7 (ADCDCCMP7), offset 0xE5C

Bit/Field	Name	Type	Reset	Description
31:28	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
27:16	COMP1	RW	0x000	Compare 1 The value in this field is compared against the ADC conversion data. The result of the comparison is used to determine if the data lies within the high-band region. Note that the value of COMP1 must be greater than or equal to the value of COMP0.
15:12	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11:0	COMP0	RW	0x000	Compare 0 The value in this field is compared against the ADC conversion data. The result of the comparison is used to determine if the data lies within the low-band region.

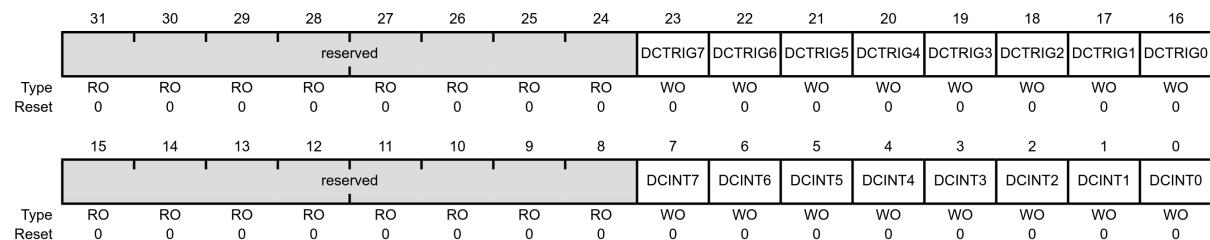

20.9.17 ADC Digital Comparator Reset Initial Conditions (ADCDCRIC)

Resetting initial conditions of digital comparators.

- Reset of triggers
- Reset of interrupts

Documentation:

- ADC0 base: 0x4003.8000
- ADC1 base: 0x4003.9000
- Offset 0xD00
- Type WO, reset 0x0000.0000

20.9.18 ADC Sample Sequence 0 Digital Comparator Select (ADCSSDC0)

This register determines which digital comparator receives the sample from the given conversion on Sample Sequence 0, if the corresponding SnDCOP bit in the **ADCSSOP0** (page 212) register is set.

- Sample sequencer can take up to eight samples.
- Each sample's digital value can be sent to a digital comparator.
- This register assigns a digital comparator to a sample.

Documentation:

- ADC0 base: 0x4003.8000
- ADC1 base: 0x4003.9000
- Offset 0x054
- Type RW, reset 0x0000.0000

20.9.19 ADC Sample Sequence 0 Operation (ADCSSOP0)

This register determines whether the sample from the given conversion on Sample Sequence 0 is saved in the Sample Sequence FIFO0 or sent to the digital comparator unit.

20.9.25 ADC Raw Interrupt Status (ADCRIS)

This register shows the status of the raw interrupt signal of each sample sequencer. These bits may be polled by software to look for interrupt conditions without sending the interrupts to the interrupt controller.

Documentation:

- ADC0 base: 0x4003.8000
- ADC1 base: 0x4003.9000
- Offset 0x004
- Type RO, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:17	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
16	INRDC	RO	0	Digital Comparator Raw Interrupt Status Value Description 0 All bits in the ADCDISC register are clear. 1 At least one bit in the ADCDISC register is set, meaning that a digital comparator interrupt has occurred.
15:4	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	INR3	RO	0	SS3 Raw Interrupt Status Value Description 0 An interrupt has not occurred. 1 A sample has completed conversion and the respective ADCSSCTL3 (page 198) IEn bit is set, enabling a raw interrupt. This bit is cleared by writing a 1 to the IN3 bit in the ADCISC register.

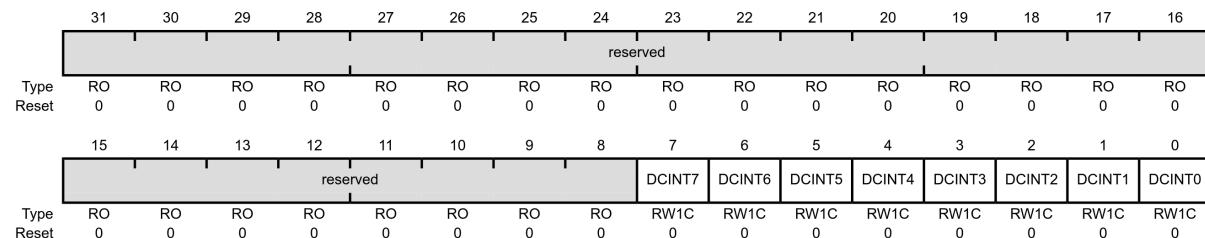

Bit/Field	Name	Type	Reset	Description

Value	Description									
0	An interrupt has not occurred.									
1	A sample has completed conversion and the respective ADCSSCTL0 IEn bit is set, enabling a raw interrupt.									

20.9.26 ADC Digital Comparator Interrupt Status and Clear (ADCDCISC)

This register provides status and acknowledgement of digital comparator interrupts. One bit is provided for each comparator.

Documentation:

- ADC0 base: 0x4003.8000
- ADC1 base: 0x4003.9000
- Offset 0x034

0	The FIFO has not overflowed.									
1	The FIFO for Sample Sequencer 0 has hit an overflow condition, meaning that the FIFO is full and a write was requested. When an overflow is detected, the most recent write is dropped.									

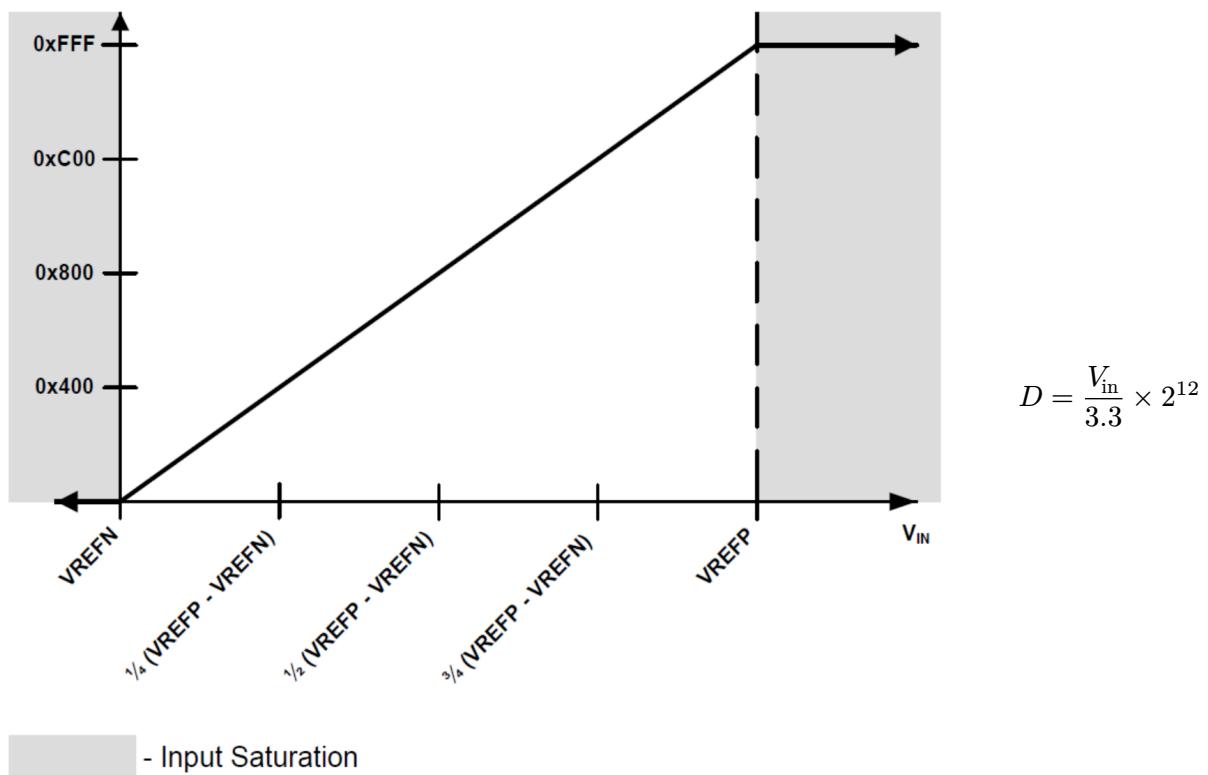

20.10 Reference voltages of Cortex M4 ADC

- 3.3 V
- Internally provided

20.11 Output from Cortex M4 ADC

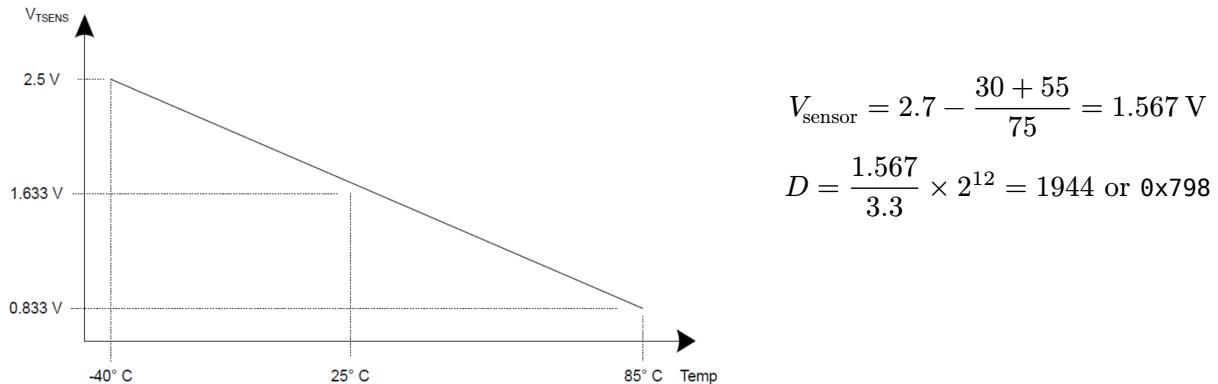

12-bit digital numbers: 0x000 to 0xFFFF

20.11.1 Exercise

The Cortex M4 has an internal temperature sensor. The temperature - voltage plot of the sensor is shown below. If the temperature is 30 °C, what is the digital output from the Cortex M4's ADC?

$$V_{TSENS} = 2.7 \text{ V} - \frac{\text{Temp} + 55}{75}$$

20.12 Initialisation

For the ADC module to be used, the following steps have to be done:

1. Enable the ADC clock using the **RCGCADC** ([page 171](#)) register.
2. Enable the clock to the appropriate GPIO modules via the **RCGCGPIO** ([page 133](#))
3. Set the **GPIOAFSEL** ([page 148](#)) bits for the ADC input pins. To determine which GPIOs to configure, see [page 164](#).
4. Configure the AINx signals to be analog inputs by **clearing** the corresponding DEN bit in the **GPIO Digital Enable** ([page 135](#)) register.
5. Disable the analogue isolation circuit for all ADC input pins that are to be used by writing a 1 to the appropriate bits of the **GPIOAMSEL** ([page 152](#)) register in the associated GPIO block.
6. If required by the application, reconfigure the sample sequencer priorities in the **ADCSSPRI** ([page 172](#)) register. The default configuration has sample sequencer 0 with the highest priority and Sample Sequencer 3 as the lowest priority.

20.12.1 Example

- Sample sequencer 3 trigger for [ADCEMUX](#) ([page 178](#)): 0xF000

20.14 Differential sampling

In addition to traditional single-ended sampling, the ADC module supports differential sampling of two analogue input channels. To enable differential sampling, software must set the Dn bit in the **ADCSSCTLn** (page 183) register in a step's configuration nibble.

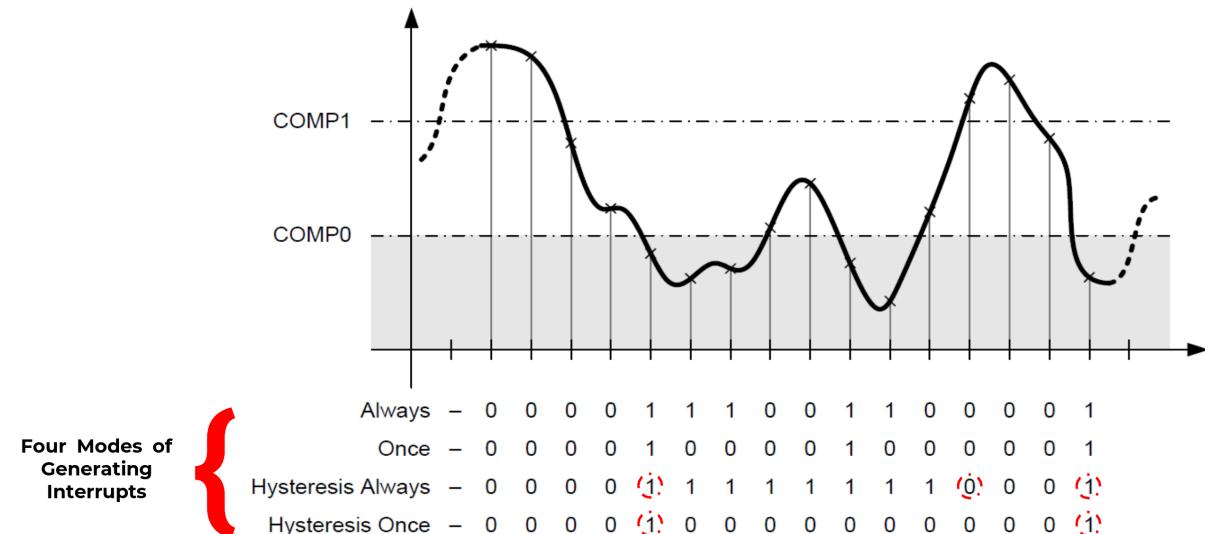

When a sequence step is configured for differential sampling, the input pair to sample must be configured in the **ADCSSMUXn** (page 175) register. Differential pair 0 samples analogue inputs 0 and 1; differential pair 1 samples analogue inputs 2 and 3; and so on. The ADC does not support other differential pairings such as analogue input 0 with analogue input 3.

20.14.1 Differential sampling pairs

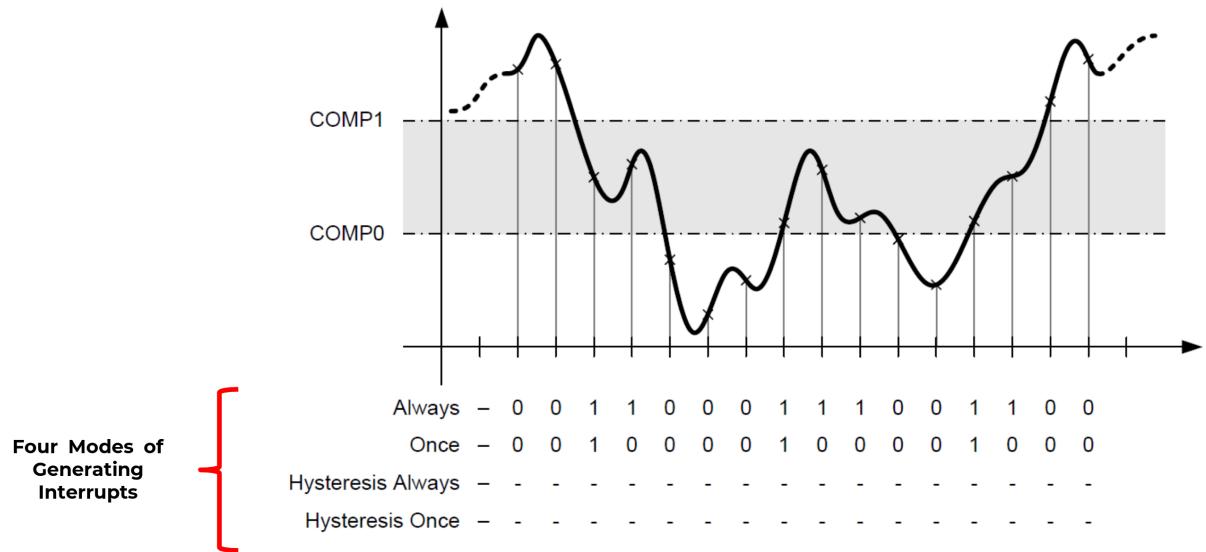

Differential Pair	Analogue Inputs
0	0 and 1
1	2 and 3
2	4 and 5
3	6 and 7
4	8 and 9
5	10 and 11

20.15 Output of interrupts

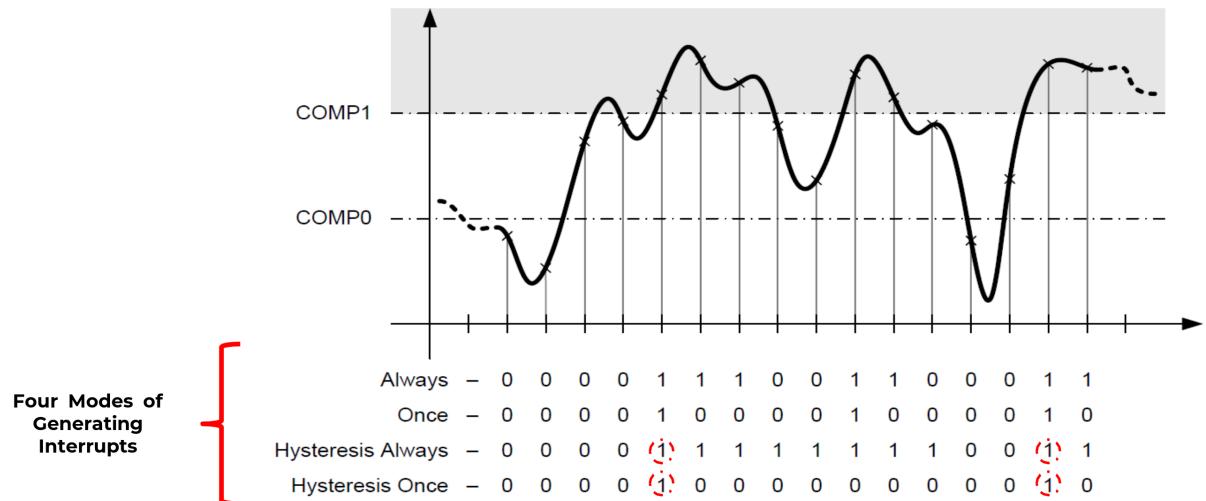

20.15.1 Low band operation

20.15.2 Mid band operation

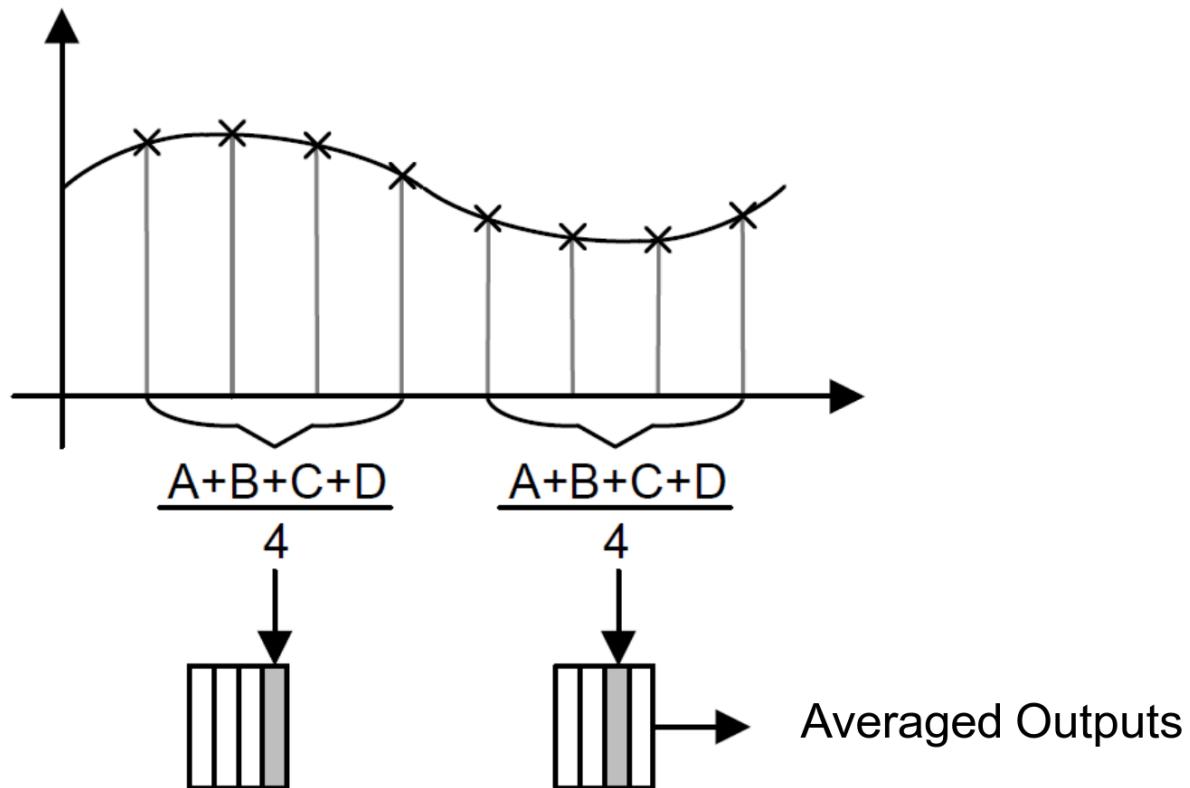

20.15.3 High band operation

20.15.4 Hardware output averaging

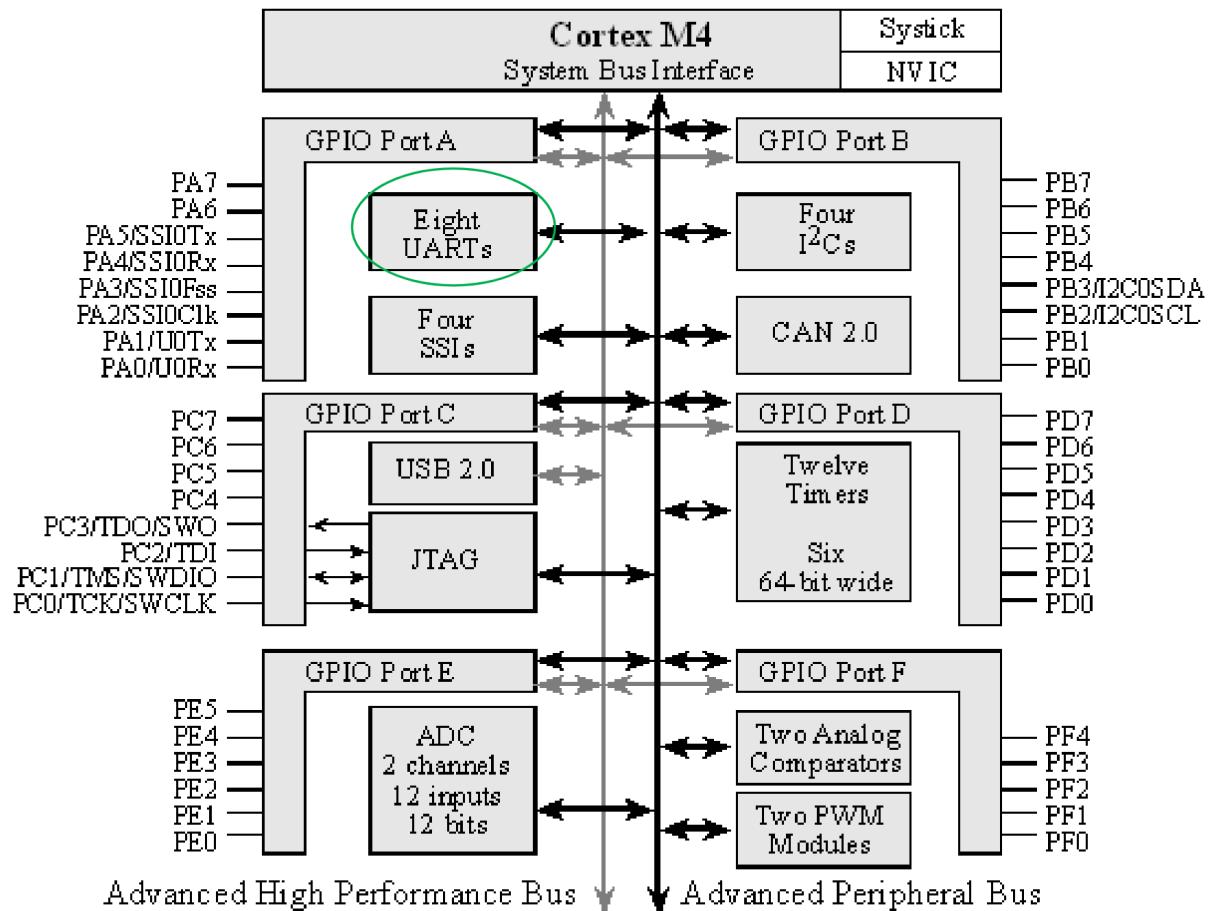

The Cortex M4 has the built-in circuit to support averaging of up to 64 digital outputs.

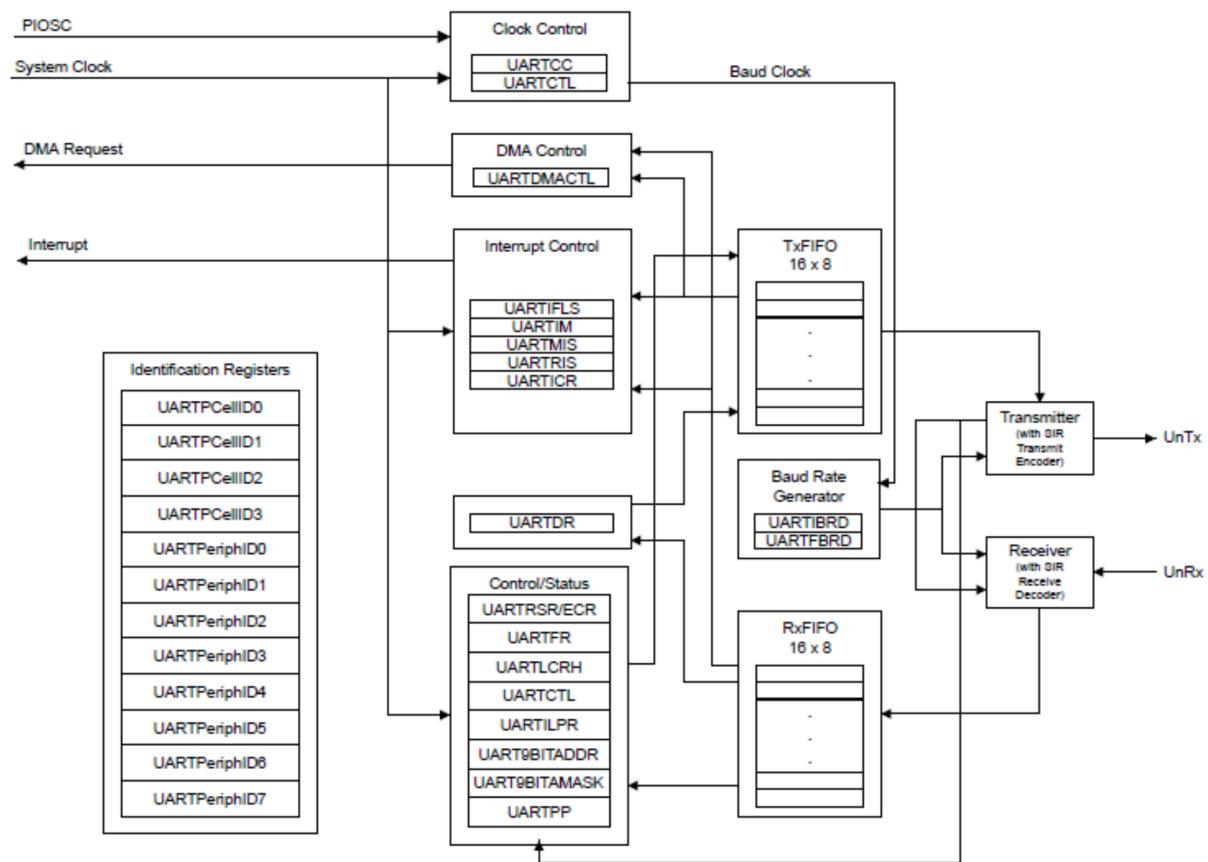

21 TM4C123GH6PM UART

- 8 Universal Asynchronous Receiver/Transmitter (UART) lines.
- Programmable baud-rate generator allowing speeds up to 5 Mbps for regular speed (divide by 16) and 10 Mbps for high speed (divide by 8).
- Separate 16x8 transmitting (TX) and receiving (RX) FIFOs to reduce the load of CPU interrupts.
- Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface.
- FIFO trigger levels of $\frac{1}{8}$, $\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$, and $\frac{7}{8}$.
- Standard asynchronous communication bits for start, stop, and parity line-break generation and detection.
- Line-break generation and detection.
- Fully programmable serial interface characteristics with 5, 6, 7 or 8 data bits.
- Even, odd, stick, or no-parity bit generation and detection.
- 1 or 2 stop bit generation.
- IrDA serial-IR (SIR) encoder/decoder providing programmable use of IrDA Serial Infrared (SIR) or UART input/output.
- Support of IrDA SIR encoder decoder functions for data rates up to 115.2 Kbps half-duplex.
- Support of normal $\frac{3}{16}$ and low-power (1.41 - 2.23 μ s) bit durations.
- Programmable internal clock generator enabling division of reference clock by 1 to 256 for low-power mode bit duration Support for communication with ISO 7816 smart cards.
- Modem flow control (on UART1).
- EIA-485 9-bit support.
- Standard FIFO-level and End-of-Transmission interrupts
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA).
 - Separate channels for transmitting and receiving.
 - Receive “single request asserted” when data is in the FIFO, and “burst request asserted” at programmed FIFO level.
- Transmit “single request asserted” when there is space in the FIFO, and “burst request asserted” at programmed FIFO level.

Value	Description									
0	μDMA for the receive FIFO is disabled.									
1	μDMA for the receive FIFO is enabled.									

21.7.7 UART Control (UARTCTL)

- UART0 base: 0x4000.C000
- UART1 base: 0x4000.D000
- UART2 base: 0x4000.E000
- UART3 base: 0x4000.F000
- UART4 base: 0x4001.0000
- UART5 base: 0x4001.1000
- UART6 base: 0x4001.2000
- UART7 base: 0x4001.3000
- Offset 0x030
- Type RW, reset 0x0000.0300

The UARTCTL register is the control register. All the bits are cleared on reset except for the Transmit Enable (TXE) and Receive Enable (RXE) bits, which are set.

- To enable the UART module, the **UARTEN** bit must be set.
- If software requires a configuration change in the module, the **UARTEN** bit must be cleared before the configuration changes are written.
- If the UART is disabled during a transmitting or receiving operation, the current transaction is completed prior to the UART stopping.
- **Note:** The **UARTCTL** ([page 255](#)) register should not be changed while the UART is enabled, otherwise the results may be unpredictable.

Making changes to the **UARTCTL** ([page 255](#)) register:

1. Disable the UART, by clearing the **UARTEN** bit.
2. Wait for the end of transmission or reception of the current character, by writing a few lines of NOP.
3. Flush the transmission FIFO by clearing bit 4 (FEN) FIFO enable in the line control register (**UARTLCRH** ([page 251](#))).
4. Reprogram the control register.
5. Enable the UART by setting the **UARTEN** bit.

21.8 Initialisation and configuration

To initialise the UART, the follow steps are necessary:

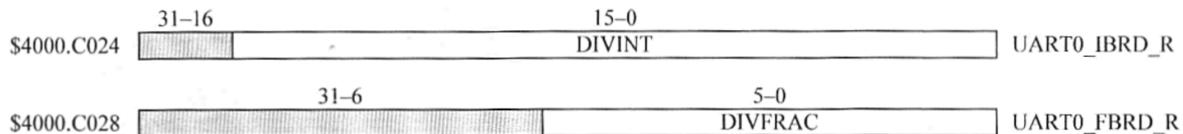

1. Enable the UART module with the **RCGCUART** ([page 247](#)) register.
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** ([page 133](#)) register.
3. Set the **GPIOAFSEL** ([page 148](#)) bits for the appropriate pins.
4. Configure the GPIO current (in mA) level and slew rate as specified for the mode selected.
5. Configure the Port Mux Control (PMCn) fields in the **GPIOPCTL** ([page 158](#)) register to assign the UART signals to the appropriate pins.
6. Write the desired serial parameters to the **UARTLCRH** ([page 251](#)) register.
7. Configure the UART clock source by writing to the **UARTCC** ([page 253](#)) register. Bits 3:0 set to 0 to use system clock.
8. Optionally, configure the µDMA channel and enable the DMA options in the **UARTDMACTL** ([page 254](#)) register.

21.9 UART baud rate settings

- When programming the UART baud rate, you need to calculate the baud-rate divider (BRD) first.
- Then the **UARTIBRD** ([page 249](#)) and **UARTFBRD** ([page 250](#)) registers are determined.
- Finally, write to the **UART Line Control (UARTLCRH)** ([page 251](#)) register.

21.10 Baud rate setting

- Registers **UARTIBRD** ([page 249](#)) and **UARTFBRD** ([page 250](#)) set the baud rate.

- 22 (16.6) bit binary fixed point value with 2^{-6} resolution.
 - **DIVINT** (integer -16 binary places)
 - **DIVFRAC** (fractional -6 binary places)
- **Baud16** clock is created with a frequency of $\frac{\text{Bus clock frequency}}{\text{Divider}}$
- **Baud16** clock is 16x of Baud rate.

$$\text{Baud rate divider} = \text{Bus clock} \div 16 \div \text{Baud rate}$$

21.10.1 Example

If the bus clock is 8 MHz, then the baud rate required is 19200 bits s^{-1} . Then:

$$\text{Baud rate divider} = 8,000,000 \div 16 \div 19200 = 26.04167$$

$$\text{Integer part : } 26 = 11010_2 = 0x1A$$

$$\text{Fractional part : } 0.04167$$

21.10.1.1 How to convert fractions in decimal to binary?

0.04167 to binary:

$$0.04167 * 2 = 0.08334 \rightarrow 0$$

$$0.08334 * 2 = 0.16668 \rightarrow 0$$

$$0.16668 * 2 = 0.33336 \rightarrow 0$$

$$0.33336 * 2 = 0.66672 \rightarrow 0$$

$$0.66672 * 2 = 1.33344 \rightarrow 1$$

$$0.33344 * 2 = 0.66688 \rightarrow 0$$

$$0.66688 * 2 = 1.33376 \rightarrow 1$$

Hence:

$$0.04167 = 0.0000101_2 \text{ or } 0.000011_2 \text{ (6 places)}$$

Faster way:

1. Multiply the fractional part by 2 to the power of the number of decimal places you need, i.e.

$$\text{Fractional part} \times 2^n$$

Where n is the number of decimal places needed.

2. Round the result to the nearest whole number and convert the result to binary.

Example:

$$\begin{aligned} 0.04167 \times 2^6 &= 2.667 \\ &\approx 3_{10} = 000011_2 = 0x03_{16} \end{aligned}$$

21.10.1.2 Continuing the example

$$26.04167 = 11010.000011_2$$

To have 19200 baud rate:

- Set UARTIBRD ([page 249](#)) to 11010 (maximum 16 places)
- Set UARTFBRD ([page 250](#)) to 000011 (maximum 6 places)

However, there is an error, as:

$$11010.000011_2 = 26\frac{3}{4} = 26.046875$$

$$\frac{26.046875}{26.04167} = 1.0002 \text{ or } 0.02\% \text{ error}$$

The baud rate must be within 5% for the channel to operate properly, otherwise a framing error will occur when the stop bit is incorrectly captured.

21.10.2 Procedure

With the baud-rate divider (BRD) values determined, the UART configuration is written to the module in the following order:

1. Disable the UART by clearing the UARTEN bit in the UARTCTL ([page 255](#)) register.
2. Write the integer portion of the BRD to the UARTIBRD ([page 249](#)) register.
3. Write the fractional portion of the BRD to the UARTFBRD ([page 250](#)) register.

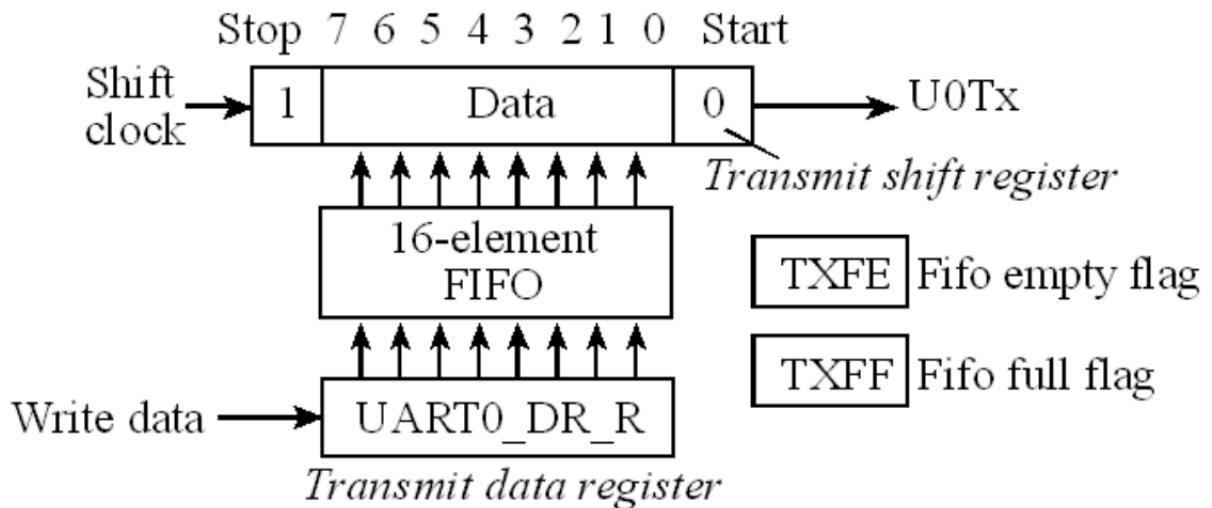

21.11 UART transmission procedure

- Enable the UART by setting the **UARTEN** bit in the **UARTCTL** (page 255) register.

- The UART is configured for transmitting or receiving via the **RXE** and **TXE** bits of the **UARTCTL** (page 255) register.
- Transmitting and receiving are both enabled out of reset. Before any control registers are programmed, the UART must be disabled by clearing the **UARTEN** bit in **UARTCTL** (page 255).
- If the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

21.12 UART transmission sequence

- Program reads **UARTFR** (page 262) that **TXFF** = 0. It will wait if **TXFF** = 1.

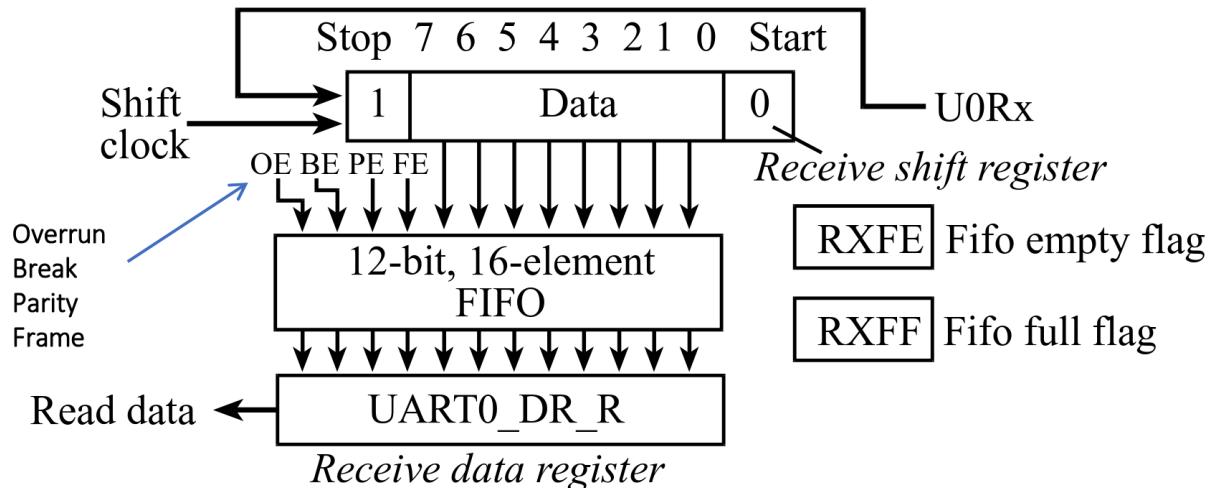

- New byte written to the **UARTDR** (page 260) register, which is then placed in the FIFO.

- 10 bit transmission shift register includes the start bit, 8 data bits, and 1 stop bit.
- The data frame is shifted out by the start bit, then from least significant bit (LSB) to most significant bit (MSB), then 1 stop bit, to the U0Tx line.

21.13 UART receiving sequence

1. 10 bit receiving shift register and 16 element FIFO, both 12 bits wide.
2. The UARTDR (page 260) register is read only when RXE bit 9 of UARTCTL (page 255) is enabled.
3. Bits from U0Rx is shifted in with the start bit, 8 data bits and then the stop bit.
4. Start and stop bits are removed and checked for framing error.
5. Program reads UARTFR (page 262) that RXFE = 0, which means the FIFO is not empty, and new data has reached the receiver.

6. 8 bits of data and 4 bits of status are put into the UARTDR (page 260) register.

7. Read the UARTDR (page 260) register bits 7:0 for the data and check the status condition bits 11:8 for errors.

22 TM4C123GH6PM SSI

The TM4C123GH6PM SSI modules have the follow features:

- Has 4 synchronous serial interface (SSI) modules.
- Programmable interface operation for Freescale SPI, MICROWIRE, or Texas Instruments.
- Synchronous serial interfaces.
- Master or slave operation.
- Programmable clock bit rate and prescaler.
- Separate transmission and reception FIFOs, each 16 bits wide and 8 locations deep.
- Programmable data frame size from 4 to 16 bits.
- Internal loopback test mode for diagnostics or debug testing.
- Standard FIFO-based interrupts and End-of-Transmission interrupt.
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA).
 - Separate channels for transmission and reception.
 - Receive “single request asserted” when data is in the FIFO, and “burst request asserted” when the FIFO contains 4 entries.
 - Transmit “single request asserted” when there is space in the FIFO, and “burst request asserted” when 4 or more entries are available to be written in the FIFO.

22.1 SSI pin names

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
SSI0Clk	19	PA2 (2)	I/O	TTL	SSI module 0 clock.
SSI0Fss	20	PA3 (2)	I/O	TTL	SSI module 0 frame signal.
SSI0Rx	21	PA4 (2)	I	TTL	SSI module 0 receive.
SSI0Tx	22	PA5 (2)	O	TTL	SSI module 0 transmit.
SSI1Clk	30	PF2 (2)	I/O	TTL	SSI module 1 clock.
	61	PD0 (2)			
SSI1Fss	31	PF3 (2)	I/O	TTL	SSI module 1 frame signal.
	62	PD1 (2)			
SSI1Rx	28	PF0 (2)	I	TTL	SSI module 1 receive.
	63	PD2 (2)			
SSI1Tx	29	PF1 (2)	O	TTL	SSI module 1 transmit.
	64	PD3 (2)			
SSI2Clk	58	PB4 (2)	I/O	TTL	SSI module 2 clock.
SSI2Fss	57	PB5 (2)	I/O	TTL	SSI module 2 frame signal.
SSI2Rx	1	PB6 (2)	I	TTL	SSI module 2 receive.
SSI2Tx	4	PB7 (2)	O	TTL	SSI module 2 transmit.
SSI3Clk	61	PD0 (1)	I/O	TTL	SSI module 3 clock.
SSI3Fss	62	PD1 (1)	I/O	TTL	SSI module 3 frame signal.
SSI3Rx	63	PD2 (1)	I	TTL	SSI module 3 receive.
SSI3Tx	64	PD3 (1)	O	TTL	SSI module 3 transmit.

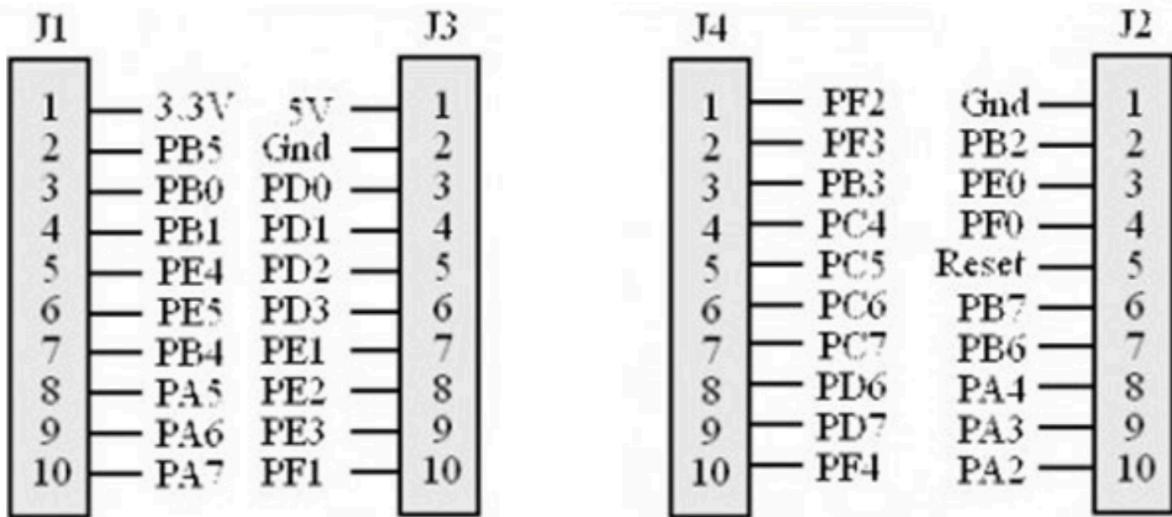

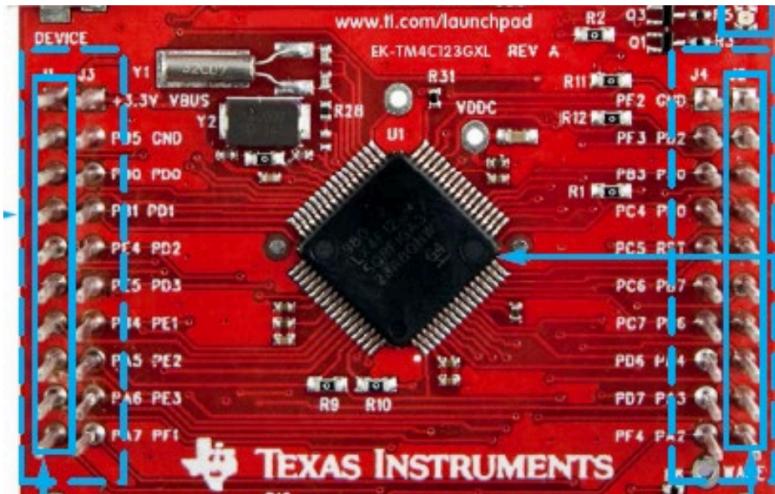

22.2 SSI module

SSI0	SSI0Tx → SSI0Rx ← SSI0Fss → SSI0Clk →
SSI1	SSI1Tx → SSI1Rx ← SSI1Fss → SSI1Clk →
SSI2	SSI2Tx → SSI2Rx ← SSI2Fss → SSI2Clk →
SSI3	SSI3Tx → SSI3Rx ← SSI3Fss → SSI3Clk →

SSI protocol has 4 I/O lines:

- SSI0Fss: Slave select is an optional negative logic control from master to slave to indicate that the channel is active.
- SSI0Clk: 50% duty cycle generated by the master.
- SSI0Tx: Data line driven by the master and received by the slave (master out, slave in, MOSI).
- SSI0Rx: Data line driven by the slave and received by the master (master in, slave out, MISO).

22.6.7 SSI Data (SSIDR)

- SSI0 base: 0x4000.8000
- SSI1 base: 0x4000.9000
- SSI2 base: 0x4000.A000
- SSI3 base: 0x4000.B000
- Offset 0x008
- Type RW, reset 0x0000.0000

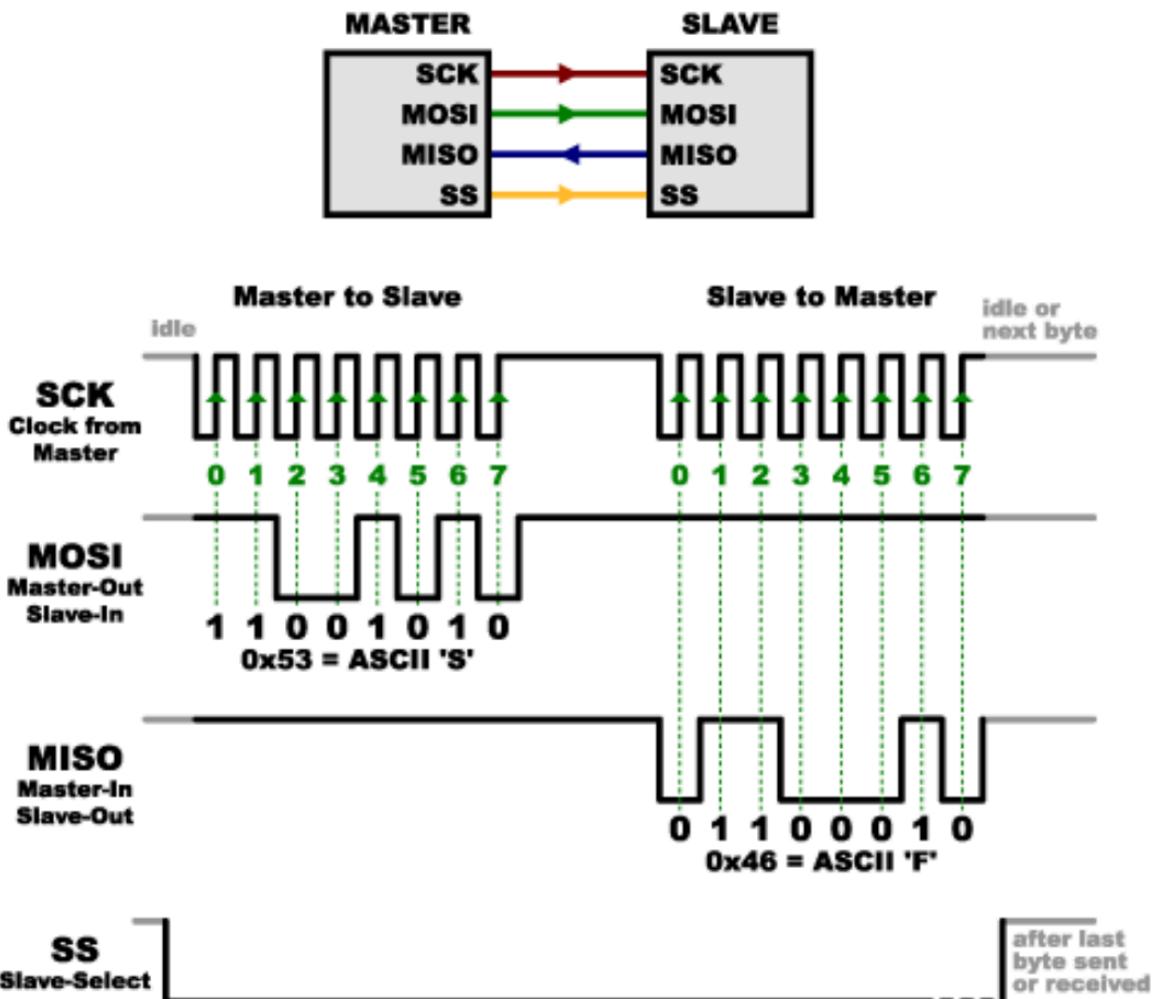

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	DATA	RW	0x0000	<p>SSI Receive/Transmit Data</p> <p>A read operation reads the receive FIFO. A write operation writes the transmit FIFO.</p> <p>Software must right-justify data when the SSI is programmed for a data size that is less than 16 bits.</p> <p>Unused bits at the top are ignored by the transmit logic.</p> <p>The receive logic automatically right-justifies the data.</p>

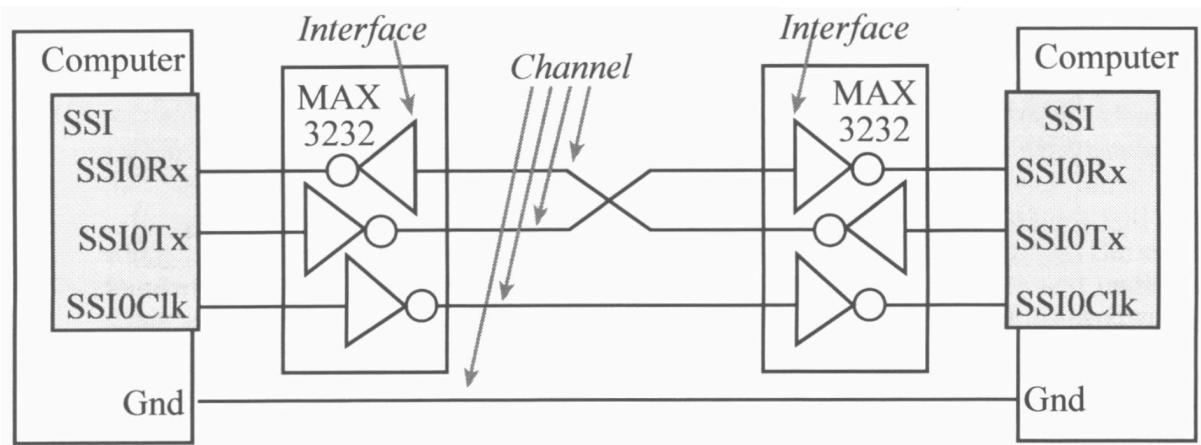

22.7 Connection to I/O device

- Serial protocols will often send the least significant bits first, so the smallest bit is on the far left. The lower nibble is actually 0011 = 0x3, and the upper nibble is 0101 = 0x5.

- The side that generates the clock is called the “master”, and the other side is called the “slave”.

- TI MAX3232 chip line driver is used to improve bandwidth, increase range and reduce noise, as well as to bring the voltages to transistor-transistor logic (TTL) requirements.

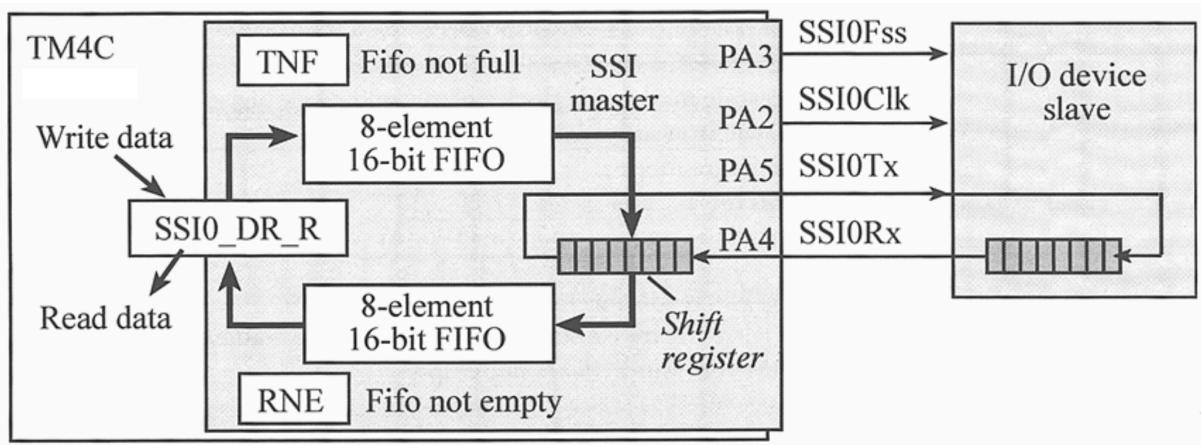

Figure 6: TM4C123G SSI connection between the microcontroller and an I/O device.

- Shift register can be configured from 4 to 16 bits (SSICR0) ([page 288](#))
- Shift register in the master and shift register in the slave are linked to form a distributed register.
- Data is written to the SSIDR ([page 297](#)) register is transmit, and is read from the SSIDR ([page 297](#)) register to receive.
- SSI on the TM4C123G has 2 16-bit FIFOs with 8 element depth.
- Data is transmitted by writing to the SSIDR ([page 297](#)) register, which puts the data in the transmission FIFO.
- Data is received by reading the SSIDR ([page 297](#)), which gets data from the receiving FIFO.
- SSI transmits and receives data at the same time.
- Data is shifted from master to slave, and from slave to master.
- Depending on the configured data of the FIFO (either 4 to 16 bits wide), data is serially shifted by 4 bits to 16 bits positions by the SCK clock, so data is exchanged between master and slave.

22.8 SSI clock frequency configuration

	31-16	15-8	7	6	5-4	3-0	
	\$4000.8000	SCR	SPH	SPO	FRF	DSS	SSI0_CRO_R

- SSI serial clock rate (frequency) set by SCR (8 bit) in the SSICR0 ([page 288](#)) register.
- SCR is any 8 bit value from 0 to 255.

\$4000.8004	7	6	5	4	3	2	1	0	SSI0_CRI1_R
\$4000.800C				BSY	SOD	MS	SSE	LBM	SSI0_SR_R
\$4000.8010					RFF	RNE	TNF	TFE	SSI0_CPSR_R
				CPSDVSR					

- Clock prescale divisor CPDVSR (8 bit) is in the SSICPSR ([page 293](#)) register.
- CPDVSR is any **even** number from 2 to 254.

$$F_{\text{bus}} = \text{Frequency of bus clock}$$

$$F_{\text{SSI}} = \frac{F_{\text{bus}}}{\text{CPDVSR} \times (1 + \text{SCR})}$$

$$\therefore \text{SSInClk} = \frac{\text{SysClk}}{\text{CPDVSR} \times (1 + \text{SCR})}$$

22.9 SSI mode control bits

- There are 3 mode control bits, MS, SP0, and SPH to configure the transmission protocol.

\$4000.8004	7	6	5	4	3	2	1	0	SSI0_CRI_R
-------------	---	---	---	---	---	---	---	---	------------

- If MS = 0, the device is set to master mode, so the device generates the SCLK line and outputs data to the SSI0Tx line and receives input on the SSI0Rx line.

\$4000.8000	31-16	15-8	7	6	5-4	3-0	DSS	SSI0_CR0_R
-------------	-------	------	---	---	-----	-----	-----	------------

- The SP0 controls polarity of the SCLK.
- The SPH controls the phase timing of the first bit to be transferred and received.
- When SPH = 0, the device will shift data on the 1st, 3rd, 5th, ... clock cycle, i.e. odd clock cycles.
- When SPH = 1, the device will shift data on the 2nd, 4th, 6th, ... clock cycle, i.e. even clock cycles.

22.10 Initialisation

1. Enable the SSI module using the **RCCGSSI** (page 296) register.
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** (page 133) register.
3. Set the **GPIOAFSEL** (page 148) bits for the appropriate pins.
4. Configure the PMCn fields in the **GPIOPCTL** (page 158) register to assign the SSI signals to the appropriate pins.
5. Program the **GPIODEN** (page 135) register to enable the pin's digital function. In addition, the drive strength, drain select and pull-up/pull-down functions must be configured.

Note: Pull-ups can be used to avoid unnecessary toggles on the SSI pins, which can take the slave into a wrong state. In addition, if the SSIClk signal is programmed to steady state High through the SP0 bit in the **SSICR0** (page 288) register, then software must also configure the GPIO port pin corresponding to the SSInClk signal as a pull-up in the **GPIO Pull-Up Select (GPIOPUR)** (page 145) register.

22.11 Configuration

For each of the frame formats, the SSI is configured using the following steps:

1. Ensure that the SSE bit in the SSICR1 ([page 290](#)) register is clear before making any configuration changes.
2. Select whether the SSI is a master or slave:
 - a. For master operations, set the SSICR1 ([page 290](#)) register to 0x0000.0000.
 - b. For slave mode (output enabled), set the SSICR1 ([page 290](#)) register to 0x0000.0004.
3. Configure the SSI clock source by writing to the SSICC ([page 292](#)) register.
4. Configure the clock prescale divisor by writing to the SSICPSR ([page 293](#)) register.
5. Write the SSICR0 ([page 288](#)) register with the following configuration:
 - Serial clock rate (SCR).
 - Desired clock phase and polarity, if using Freescale SPI mode (SPH and SP0).
 - The protocol mode: Freescale SPI, TI SSF, MICROWAVE (FRF).
 - The data size (DSS).
6. Enable the SSI by setting the SSE bit in the SSICR1 ([page 290](#)) register.

22.11.1 Example

The SSI must be configured to operate with the following parameters:

- Master operation
- Freescale SPI mode (SP0 = 1, SPH = 1)
- 1 Mbps bit rate
- 8 data bits

Assuming the system clock is 20 MHz, the bit rate calculation would be:

$$\text{SSIInClk} = \frac{\text{SysClk}}{\text{CPSDVSR} \times (1 + \text{SCR})}$$

$$1 \times 10^6 = \frac{20 \times 10^6}{\text{CPSDVSR} \times (1 + \text{SCR})}$$

In this case, if CPSDVSR = 0x2, SCR must be 0x9.

The configuration sequence would be as follows:

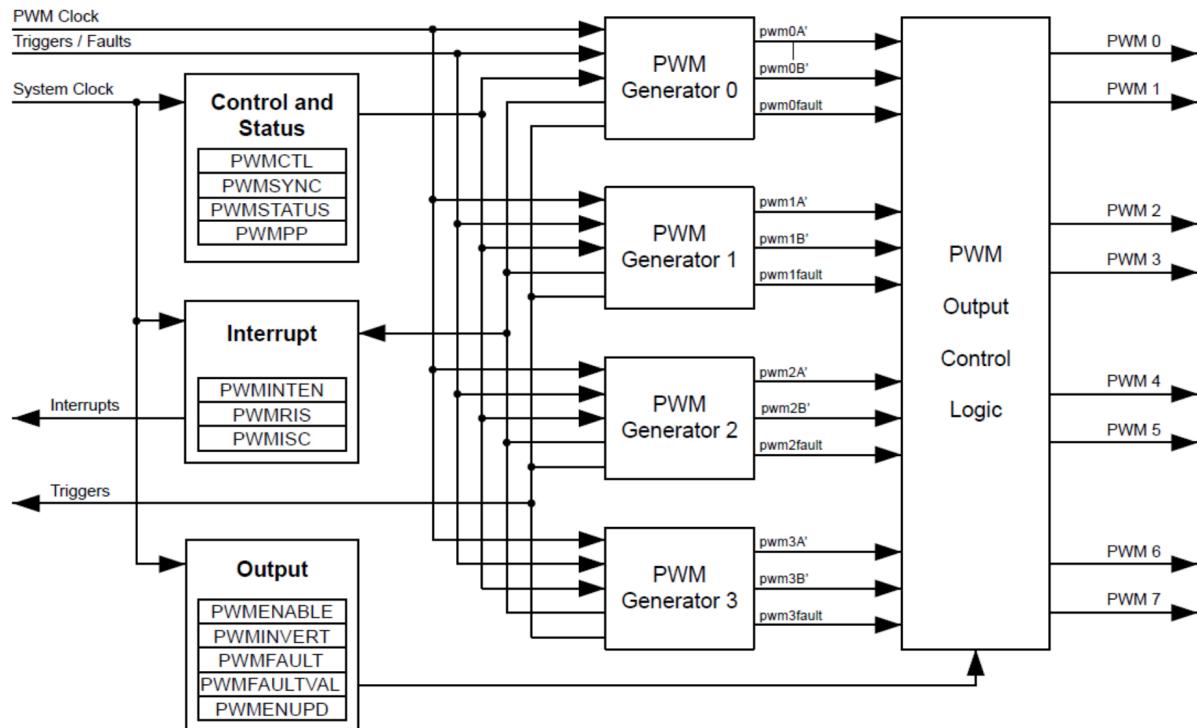

1. Ensure that the SSE bit in the SSICR1 ([page 290](#)) register is clear.
2. Write to the SSICR1 (SSI control) ([page 290](#)) register with a value of 0x0000.0000, which disables SSI.
3. Write to the SSICPSR (SSI clock prescale) ([page 293](#)) register with a value of 0x0000.0002.
4. Write the SSICR0 (SSI control 0) ([page 288](#)) register with a value of 0x0000.09C7.
5. The SSI is then enabled by setting the SSE bit in the SSICR1 ([page 290](#)) register.

23 TM4C123GH6PM PWM

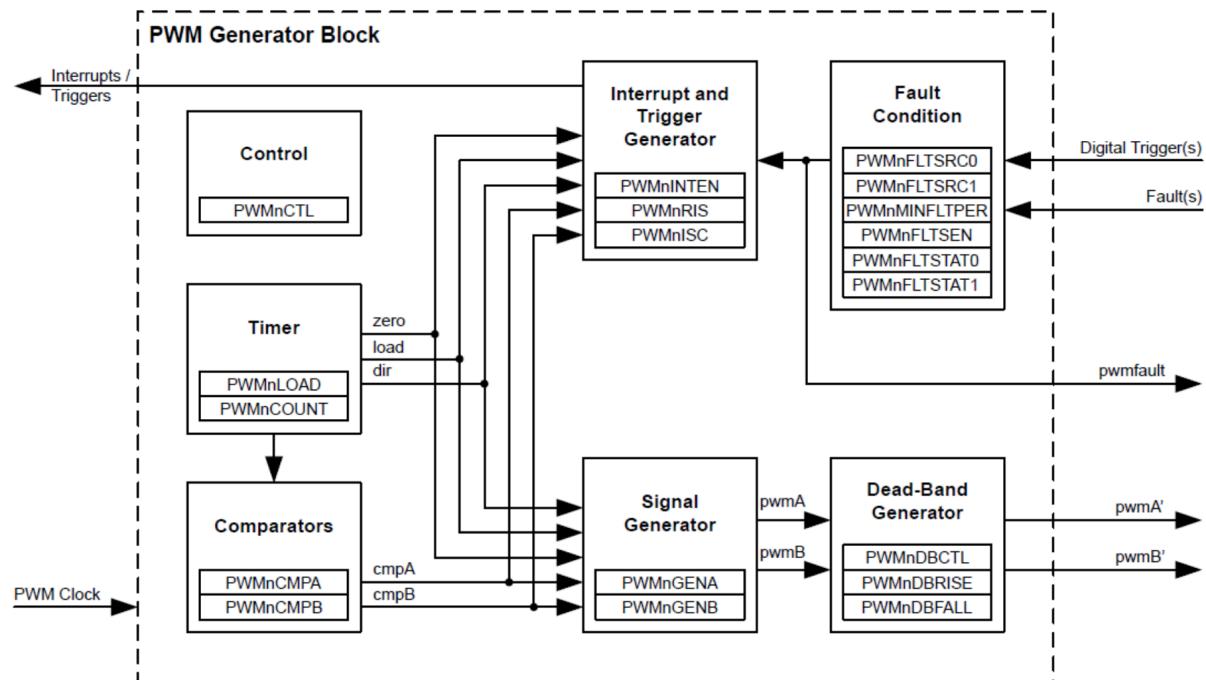

- 2 PWM modules.
- Each PWM module has 4 generator blocks and a control block.
- Each generator block can produce 2 PWM signals, so the total is $2 \times 4 \times 2 = 16$ PWM outputs.
- Each generator block has:
 - One fault-condition handling inputs to quickly provide low-latency shutdown and prevent damage to the motor being controlled, for a total of two inputs.
 - One 16-bit counter.
 - The ability to run in down or up/down mode.
 - Has output frequency controlled by a 16-bit load value.
 - Load value updates that can be synchronised.
 - The ability to produce output signals at zero and load value.
 - Two PWM comparators.
 - Optional output inversion of each PWM signal, or polarity control.
 - Optional fault handling for each PWM signal.
 - Synchronisation of timers in the PWM generator blocks.
 - Synchronisation of timer or comparator updates across the PWM generator blocks.
 - Extended PWM synchronisation of timer or comparator updates across the PWM generator blocks.
 - Interrupt status summary of the PWM generator blocks.
 - Extended PWM fault handling, with multiple fault signals, programmable polarities, and filtering.
 - PWM generators can be operated independently or synchronised with other generators.

23.1 Block diagrams

23.1.1 PWM module

23.1.2 PWM generator block

23.2 PWM pins

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
M0FAULT0	30	PF2 (4)	I	TTL	Motion Control Module 0 PWM Fault 0.
	53	PB6 (4)			
	63	PD2 (4)			
M0PWM0	1	PB6 (4)	O	TTL	Motion Control Module 0 PWM 0. This signal is controlled by Module 0 PWM Generator 0.
M0PWM1	4	PB7 (4)	O	TTL	Motion Control Module 0 PWM 1. This signal is controlled by Module 0 PWM Generator 0.
M0PWM2	58	PB4 (4)	O	TTL	Motion Control Module 0 PWM 2. This signal is controlled by Module 0 PWM Generator 1.
M0PWM3	57	PB5 (4)	O	TTL	Motion Control Module 0 PWM 3. This signal is controlled by Module 0 PWM Generator 1.
M0PWM4	59	PE4 (4)	O	TTL	Motion Control Module 0 PWM 4. This signal is controlled by Module 0 PWM Generator 2.
M0PWM5	60	PE5 (4)	O	TTL	Motion Control Module 0 PWM 5. This signal is controlled by Module 0 PWM Generator 2.
M0PWM6	16	PC4 (4)	O	TTL	Motion Control Module 0 PWM 6. This signal is controlled by Module 0 PWM Generator 3.
	61	PD0 (4)			
M0PWM7	15	PC5 (4)	O	TTL	Motion Control Module 0 PWM 7. This signal is controlled by Module 0 PWM Generator 3.
	62	PD1 (4)			
M1FAULT0	5	PF4 (5)	I	TTL	Motion Control Module 1 PWM Fault 0.
M1PWM0	61	PD0 (5)	O	TTL	Motion Control Module 1 PWM 0. This signal is controlled by Module 1 PWM Generator 0.

Pin Name	Pin Number	Pin Mux / Pin Assignment	Pin Type	Buffer Type	Description
M1PWM1	62	PD1 (5)	O	TTL	Motion Control Module 1 PWM 1. This signal is controlled by Module 1 PWM Generator 0.
M1PWM2	23	PA6 (5)	O	TTL	Motion Control Module 1 PWM 2. This signal is controlled by Module 1 PWM Generator 1.
	59	PE4 (5)			
M1PWM3	24	PA7 (5)	O	TTL	Motion Control Module 1 PWM 3. This signal is controlled by Module 1 PWM Generator 1.
	60	PE5 (5)			
M1PWM4	28	PF0 (5)	O	TTL	Motion Control Module 1 PWM 4. This signal is controlled by Module 1 PWM Generator 2.
M1PWM5	29	PF1 (5)	O	TTL	Motion Control Module 1 PWM 5. This signal is controlled by Module 1 PWM Generator 2.
M1PWM6	30	PF2 (5)	O	TTL	Motion Control Module 1 PWM 6. This signal is controlled by Module 1 PWM Generator 3.
M1PWM7	31	PF3 (5)	O	TTL	Motion Control Module 1 PWM 7. This signal is controlled by Module 1 PWM Generator 3.

Clearing the INTFAULTn bit clears the fault condition.</td> </tr> </tbody> </table> <p>Note: When using an ADC digital comparator as a fault source, the LATCH and MINFLTPER bits in the PWMnCTL (page 322) register should be set to 1 to ensure trigger assertions are captured.</p>		Value	Description	0	Fault Condition Not Latched A fault condition is in effect for as long as the generating source is asserting.	1	Fault Condition Latched A fault condition is set as the result of the assertion of the faulting source and is held (latched) while the PWMISETC (page 380) INTFAULTn bit is set. Clearing the INTFAULTn bit clears the fault condition.
Value	Description										
0	Fault Condition Not Latched A fault condition is in effect for as long as the generating source is asserting.										
1	Fault Condition Latched A fault condition is set as the result of the assertion of the faulting source and is held (latched) while the PWMISETC (page 380) INTFAULTn bit is set. Clearing the INTFAULTn bit clears the fault condition.										

Bit/Field	Name	Type	Reset	Description						
17	MINFLTPER	RW	0	<p>Minimum Fault Period</p> <p>This bit specifies that the PWM generator enables a one-shot counter to provide a minimum fault condition period.</p> <p>The timer begins counting on the rising edge of the fault condition to extend the condition to the minimum duration of the count value. The timer ignores the state of the fault condition while counting.</p> <p>The minimum fault delay is in effect only when the MINFLTPER bit is set. If a detected fault is in the process of being extended when the MINFLTPER bit is cleared, the fault condition extension is aborted.</p> <p>The delay time is specified by the PWMnMINFLTPER register MFF field value. The effect of this is to pulse stretch the fault condition input.</p> <p>The delay value is defined by the PWM clock period. Because the fault input is not synchronized to the PWM clock, the period of the time is PWMnCLOCK (MFFP value + 1) or PWMnCLOCK (MFFP value + 2).</p> <p>The delay function makes sense only if the fault source is unlatched. A latched fault source makes the fault condition appear asserted until cleared by software and negates the utility of the extend feature. It applies to all fault condition sources as specified in the FLTSRC field.</p> <table> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>0</td><td>The FAULT input deassertion is unaffected.</td></tr> <tr> <td>1</td><td>The PWMnMINFLTPER (page 349) one-shot counter is active and extends the period of the fault condition to a minimum period.</td></tr> </tbody> </table> <p>Note: When using an ADC digital comparator as a fault source, the LATCH and MINFLTPER bits in the PWMnCTL (page 322) register should be set to 1 to ensure trigger assertions are captured.</p>	Value	Description	0	The FAULT input deassertion is unaffected.	1	The PWMnMINFLTPER (page 349) one-shot counter is active and extends the period of the fault condition to a minimum period.
Value	Description									
0	The FAULT input deassertion is unaffected.									
1	The PWMnMINFLTPER (page 349) one-shot counter is active and extends the period of the fault condition to a minimum period.

Value	Description									
0	The MnPWM0 signal has a zero value.									
1	The generated pwm0A' signal is passed to the MnPWM0 pin.									

23.4.11 PWMn Dead-Band Rising-Edge Delay (PWMnDBRISE)

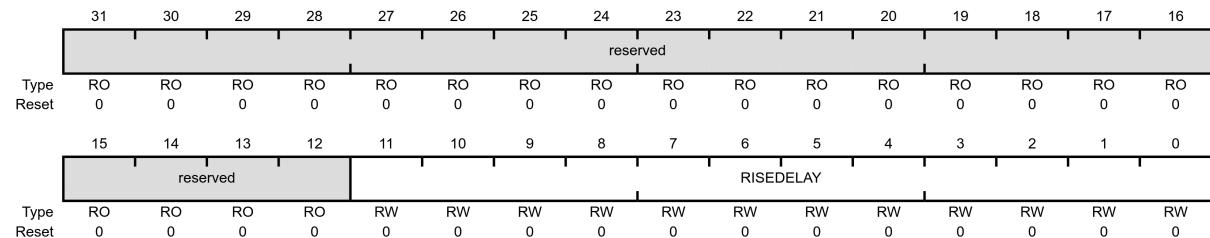

This register sets the dead-band rising delay.

Documentation:

- PWM0 base: 0x4002.8000
- PWM1 base: 0x4002.9000
- Offset 0x06C
- Type RW, reset 0x0000.0000

Registers:

- Register 56: PWM0 Dead-Band Rising-Edge Delay (PWM0DBRISE), offset 0x06C
- Register 57: PWM1 Dead-Band Rising-Edge Delay (PWM1DBRISE), offset 0x0AC
- Register 58: PWM2 Dead-Band Rising-Edge Delay (PWM2DBRISE), offset 0x0EC
- Register 59: PWM3 Dead-Band Rising-Edge Delay (PWM3DBRISE), offset 0x12C

Bit/Field	Name	Type	Reset	Description
31:12	reserved	RO	0x0000.0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11:0	RISEDELAY	RW	0x000	Dead-Band Rise Delay The number of clock cycles to delay the rising edge of pwmA' after the rising edge of pwmA.

23.4.12 PWMn Dead-Band Falling-Edge-Delay (PWMnDBFALL)

This register sets the dead-band falling delay.

Documentation:

- PWM0 base: 0x4002.8000
- PWM1 base: 0x4002.9000
- Offset 0x070
- Type RW, reset 0x0000.0000

Registers:

- Register 60: PWM0 Dead-Band Falling-Edge-Delay (PWM0DBFALL), offset 0x070
- Register 61: PWM1 Dead-Band Falling-Edge-Delay (PWM1DBFALL), offset 0x0B0
- Register 62: PWM2 Dead-Band Falling-Edge-Delay (PWM2DBFALL), offset 0x0F0
- Register 63: PWM3 Dead-Band Falling-Edge-Delay (PWM3DBFALL), offset 0x130

31:12	reserved	RO	0x0000.0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
11:0	FALLDELAY	RW	0x000	Dead-Band Fall Delay The number of clock cycles to delay the falling edge of pwmB' from the rising edge of pwmA.

23.4.13 PWMn Fault Source 0 (PWMnFLTSRC0)

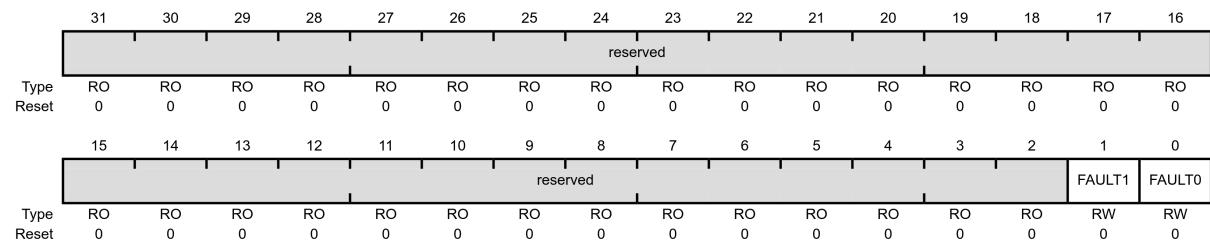

This register enables the PWM's fault source 0, which has 2 fault input pins. It specifies which fault pin inputs are used to generate a fault condition. Each bit in this register indicates whether the corresponding fault pin is included in the fault condition.

Documentation:

- PWM0 base: 0x4002.8000
- PWM1 base: 0x4002.9000
- Offset 0x074
- Type RW, reset 0x0000.0000

Registers:

- Register 64: PWM0 Fault Source 0 (PWM0FLTSRC0), offset 0x074
- Register 65: PWM1 Fault Source 0 (PWM1FLTSRC0), offset 0x0B4
- Register 66: PWM2 Fault Source 0 (PWM2FLTSRC0), offset 0x0F4
- Register 67: PWM3 Fault Source 0 (PWM3FLTSRC0), offset 0x134

23.4.14 PWMn Fault Source 1 (PWMnFLTSRC1)

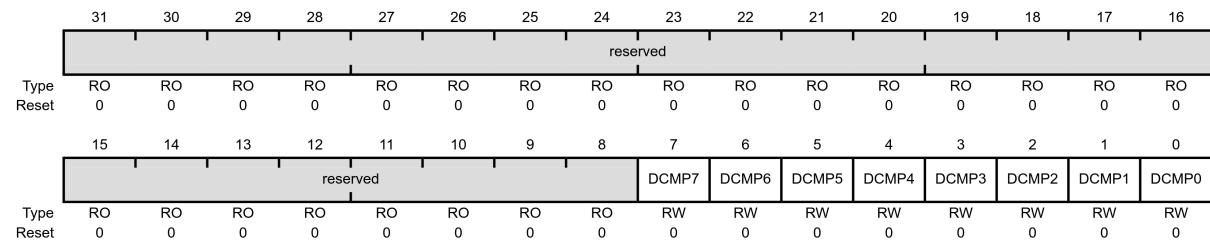

This register enables the PWM's fault source 1, which contains ADC's 8 digital comparators. It also specifies which digital comparator triggers from the ADC are used to generate a fault condition. Each bit in this register indicates whether the corresponding digital comparator trigger is included in the fault condition.

Documentation:

- PWM0 base: 0x4002.8000
- PWM1 base: 0x4002.9000
- Offset 0x078
- Type RW, reset 0x0000.0000

Registers:

23.4.15 PWMn Dead-Band Control (PWMnDBCTL)

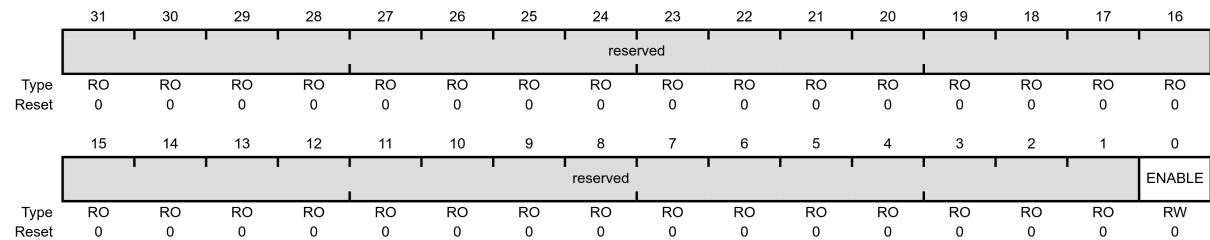

This register enables the use of the PWM's dead-band between pulses A' and B'.

Documentation:

- PWM0 base: 0x4002.8000
- PWM1 base: 0x4002.9000
- Offset 0x068
- Type RW, reset 0x0000.0000

Registers:

- Register 52: PWM0 Dead-Band Control (PWM0DBCTL), offset 0x068
- Register 53: PWM1 Dead-Band Control (PWM1DBCTL), offset 0x0A8
- Register 54: PWM2 Dead-Band Control (PWM2DBCTL), offset 0x0E8
- Register 55: PWM3 Dead-Band Control (PWM3DBCTL), offset 0x128

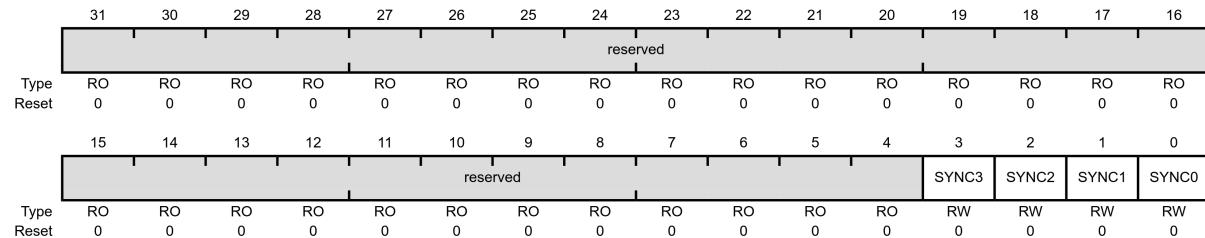

Bit/Field	Name	Type	Reset	Description						
31:1	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Value	Description									
0	The pwmA and pwmB signals pass through to the pwmA' and pwmB' signals unmodified.									
1	The dead-band generator modifies the pwmA signal by inserting dead bands into the pwmA' and pwmB' signals.									

23.4.16 PWM Time Base Sync (PWMSYNC)

This register provides a method to perform synchronisation of the counters in the PWM generation blocks. Setting a bit in this register causes the specified counter to reset back to 0.

Documentation:

- PWM0 base: 0x4002.8000
- PWM1 base: 0x4002.9000
- Offset 0x004
- Type RW, reset 0x0000.0000

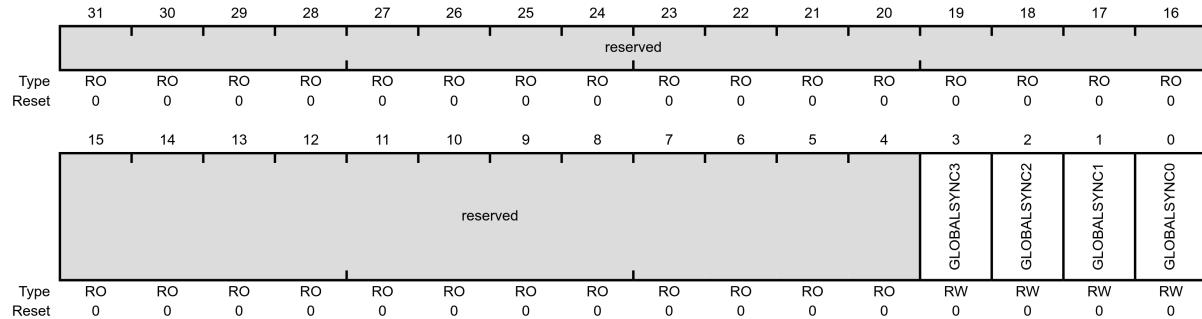

Bit/Field	Name	Type	Reset	Description
31:4	reserved	RO	0x000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
3	SYNC3	RW	0	Reset Generator 3 Counter Value Description 0 No effect. 1 Resets the PWM generator 3 counter.
2	SYNC2	RW	0	Reset Generator 2 Counter Value Description 0 No effect. 1 Resets the PWM generator 2 counter.
1	SYNC1	RW	0	Reset Generator 1 Counter Value Description 0 No effect. 1 Resets the PWM generator 1 counter.
0	SYNC0	RW	0	Reset Generator 0 Counter Value Description 0 No effect. 1 Resets the PWM generator 0 counter.

23.4.17 PWM Master Control (PWMCTL)

This register provides master control over the PWM generation blocks.

Documentation:

- PWM0 base: 0x4002.8000
- PWM1 base: 0x4002.9000
- Offset 0x000
- Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description						
31:4	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

Value	Description									
0	No effect.									
1	Any queued update to a load or comparator register in PWM generator 0 is applied the next time the corresponding counter becomes zero.									

23.4.18 PWMn Minimum Fault Period (PWMrMINFLTPER)

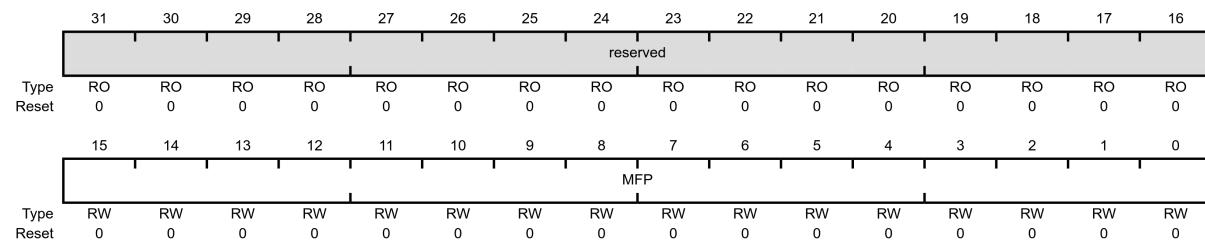

This register sets the minimum delay period before releasing the fault condition. It specifies the 16-bit time extension value to be used in extending the fault condition.

Documentation:

- PWM0 base: 0x4002.8000
- PWM1 base: 0x4002.9000
- Offset 0x07C
- Type RW, reset 0x0000.0000

Registers:

- Register 72: PWM0 Minimum Fault Period (PWMrMINFLTPER), offset 0x07C
- Register 73: PWM1 Minimum Fault Period (PWMrMINFLTPER), offset 0x0BC
- Register 74: PWM2 Minimum Fault Period (PWMrMINFLTPER), offset 0x0FC
- Register 75: PWM3 Minimum Fault Period (PWMrMINFLTPER), offset 0x13C

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	MFP	RW	0x0000	Minimum Fault Period The number of PWM clocks by which a fault condition is extended when the delay is enabled by PWMrCTL (page 322) MINFLIPER.

23.4.19 PWMn Fault Pin Logic Sense (PWMnFLTSEN)

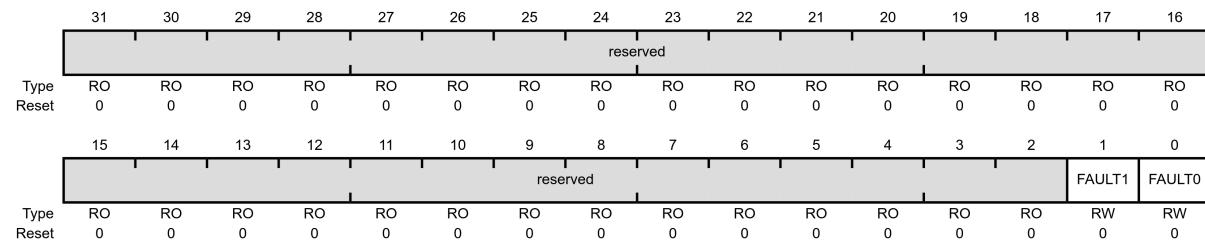

This register defines the PWM fault pin logic sense.

Documentation:

- PWM0 base: 0x4002.8000
- PWM1 base: 0x4002.9000
- Offset 0x800
- Type RW, reset 0x0000.0000

Registers:

- Register 76: PWM0 Fault Pin Logic Sense (PWM0FLTSEN), offset 0x800
- Register 77: PWM1 Fault Pin Logic Sense (PWM1FLTSEN), offset 0x880

Bit/Field	Name	Type	Reset	Description						
31:2	reserved	RO	0x0000.000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.						
1	FAULT1	RW	0	<p>Fault1 Sense</p> <table> <tr> <td>Value</td> <td>Description</td> </tr> <tr> <td>0</td> <td>An error is indicated if the Fault1 signal is High.</td> </tr> <tr> <td>1</td> <td>An error is indicated if the Fault1 signal is Low.</td> </tr> </table>	Value	Description	0	An error is indicated if the Fault1 signal is High.	1	An error is indicated if the Fault1 signal is Low.
Value	Description									
0	An error is indicated if the Fault1 signal is High.									
1	An error is indicated if the Fault1 signal is Low.									
0	FAULT0	RW	0	<p>Fault0 Sense</p> <table> <tr> <td>Value</td> <td>Description</td> </tr> <tr> <td>0</td> <td>An error is indicated if the Fault0 signal is High.</td> </tr> <tr> <td>1</td> <td>An error is indicated if the Fault0 signal is Low.</td> </tr> </table>	Value	Description	0	An error is indicated if the Fault0 signal is High.	1	An error is indicated if the Fault0 signal is Low.
Value	Description									
0	An error is indicated if the Fault0 signal is High.									
1	An error is indicated if the Fault0 signal is Low.									

23.4.20 PWM Enable Update (PWMENUPD)

This register specifies when updates to the **PWMnEN** bit in **PWMENABLE** (page 335) register are performed.

Documentation:

- PWM0 base: 0x4002.8000
- PWM1 base: 0x4002.9000
- Offset 0x028
- Type RW, reset 0x0000.0000

23.4.21 PWM Output Inversion (PWMINVERT)

This register provides a master control of the polarity of the MnPWMn signals on the device pins.

Documentation:

- PWM0 base: 0x4002.8000
- PWM1 base: 0x4002.9000
- Offset 0x00C
- Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description						
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

3	FAULT3	RW	0	MnPWM3 Fault Value Description 0 The generated pwm1B' signal is passed to the MnPWM3 pin. 1 The MnPWM3 output signal is driven to the value specified by the PWM3 bit in the PWMFAULTVAL (page 360) register.
2	FAULT2	RW	0	MnPWM2 Fault Value Description 0 The generated pwm1A' signal is passed to the MnPWM2 pin. 1 The MnPWM2 output signal is driven to the value specified by the PWM2 bit in the PWMFAULTVAL (page 360) register.
1	FAULT1	RW	0	MnPWM1 Fault Value Description 0 The generated pwm0B' signal is passed to the MnPWM1 pin. 1 The MnPWM1 output signal is driven to the value specified by the PWM1 bit in the PWMFAULTVAL (page 360) register.
0	FAULT0	RW	0	MnPWM0 Fault Value Description 0 The generated pwm0A' signal is passed to the MnPWM0 pin. 1 The MnPWM0 output signal is driven to the value specified by the PWM0 bit in the PWMFAULTVAL (page 360) register.

23.4.23 PWM Fault Condition Value (PWMFAULTVAL)

This register sets the output value (high or low) of fault conditions. It specifies the output value driven on the MnPWM_n signals during a fault condition if enabled by the corresponding bit in the **PWMFAULT** (page 358) register.

Documentation:

- PWM0 base: 0x4002.8000
- PWM1 base: 0x4002.9000
- Offset 0x024
- Type RW, reset 0x0000.0000

23.4.27 PWMn Fault Status 0 (PWMnFLTSTAT0)

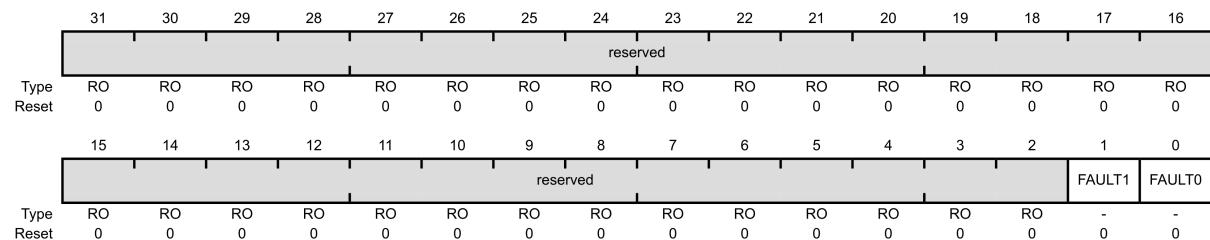

- PWM0 base: 0x4002.8000
- PWM1 base: 0x4002.9000
- Offset 0x804
- Type -, reset 0x0000.0000

Registers:

- Register 78: PWM0 Fault Status 0 (PWM0FLTSTAT0), offset 0x804
- Register 79: PWM1 Fault Status 0 (PWM1FLTSTAT0), offset 0x884
- Register 80: PWM2 Fault Status 0 (PWM2FLTSTAT0), offset 0x904
- Register 81: PWM3 Fault Status 0 (PWM3FLTSTAT0), offset 0x984

Along with the **PWMnFLTSTAT1** (page 373) register, this register provides status regarding the fault condition inputs.

If in unlatched mode, FAULT1 and FAULT0 indicate the status of fault conditions (read-only). If in latched mode, FAULT1 and FAULT0 indicate the status of fault conditions and can be cleared.

Bit/Field	Name	Type	Reset	Description
31:2	reserved	RO	0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
1	FAULT1	-	0	<p>Fault Input 1</p> <p>If the PWMnCTL (page 322) register LATCH bit is clear, this bit is RO and represents the current state of the MnFAULT1 input signal after the logic sense adjustment.</p> <p>If the PWMnCTL (page 322) register LATCH bit is set, this bit is RW1C and represents a sticky version of the MnFAULT1 input signal after the logic sense adjustment.</p> <ul style="list-style-type: none"> • If FAULT1 is set, the input transitioned to the active state previously. • If FAULT1 is clear, the input has not transitioned to the active state since the last time it was cleared. • The FAULT1 bit is cleared by writing it with the value 1.

Bit/Field	Name	Type	Reset	Description
0	FAULT0	-	0	<p>Fault Input 0</p> <p>If the PWMnCTL (page 322) register LATCH bit is clear, this bit is RO and represents the current state of the input signal after the logic sense adjustment.</p> <p>If the PWMnCTL (page 322) register LATCH bit is set, this bit is RW1C and represents a sticky version of the input signal after the logic sense adjustment.</p> <ul style="list-style-type: none"> • If FAULT0 is set, the input transitioned to the active state previously. • If FAULT0 is clear, the input has not transitioned to the active state since the last time it was cleared. • The FAULT0 bit is cleared by writing it with the value 1.

23.4.28 PWMn Fault Status 1 (PWMnFLTSTAT1)

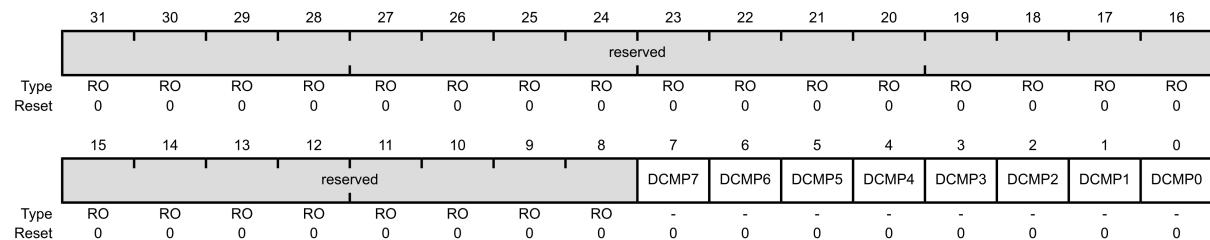

- PWM0 base: 0x4002.8000
- PWM1 base: 0x4002.9000
- Offset 0x808
- Type -, reset 0x0000.0000

Registers:

- Register 82: PWM0 Fault Status 1 (PWM0FLTSTAT1), offset 0x808
- Register 83: PWM1 Fault Status 1 (PWM1FLTSTAT1), offset 0x888
- Register 84: PWM2 Fault Status 1 (PWM2FLTSTAT1), offset 0x908
- Register 85: PWM3 Fault Status 1 (PWM3FLTSTAT1), offset 0x988

Along with the **PWMnFLTSTAT0** (page 371) register, this register provides status regarding the fault condition inputs.

If in unlatched mode, bits 0 to 7 indicate the status of fault conditions (read-only). If in latched mode, bits 0 to 7 indicate the status of fault conditions and can be cleared.

Bit/Field	Name	Type	Reset	Description
31:8	reserved	RO	0x0000.00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

23.4.29 PWMn Counter (PWMnCOUNT)

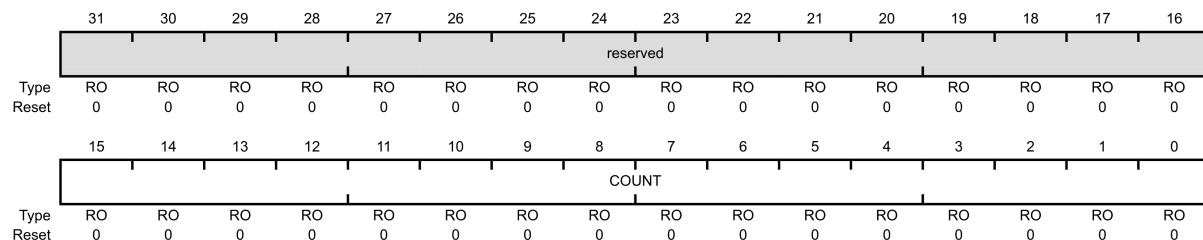

These registers contain the current value of the PWM counter (**PWM0COUNT** (page 376) is the value of the PWM generator 0 block, and so on).

Documentation:

- PWM0 base: 0x4002.8000
- PWM1 base: 0x4002.9000
- Offset 0x054
- Type RO, reset 0x0000.0000

Registers:

- Register 32: PWM0 Counter (PWM0COUNT), offset 0x054
- Register 33: PWM1 Counter (PWM1COUNT), offset 0x094
- Register 34: PWM2 Counter (PWM2COUNT), offset 0x0D4
- Register 35: PWM3 Counter (PWM3COUNT), offset 0x114

Bit/Field	Name	Type	Reset	Description
31:16	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:0	COUNT	RO	0x0000	<p>Counter Value</p> <p>The current value of the counter.</p>

23.4.30 PWM Raw Interrupt Status (PWMRIS)

This register provides the current set of interrupt sources that are asserted, regardless of whether they are enabled to cause an interrupt to be asserted to the interrupt controller.

Documentation:

- PWM0 base: 0x4002.8000
- PWM1 base: 0x4002.9000
- Offset 0x018
- Type RO, reset 0x0000.0000

0	The fault condition for PWM generator 0 is not asserted.									
1	The fault condition for PWM generator 0 is asserted. If the FLTSRC bit in the PWM0CTL (page 322) register is clear, the input is the source of the fault condition, and is therefore asserted.									

23.5 PWM module clock source

Each of the Cortex M4's two PWM module has two clock sources:

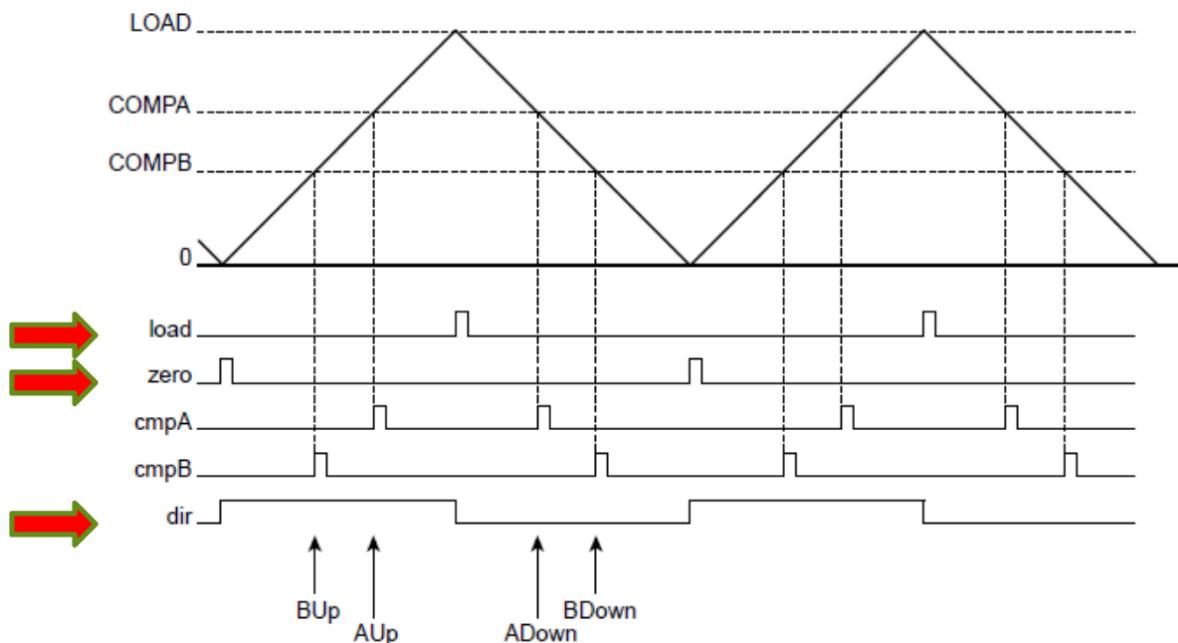

- System clock (TM4C123GH6PM's system clock is 80 MHz)
- PWM clock, which is a pre-divided system clock ($\frac{80 \text{ MHz}}{64}$ (default))

The clock source is selected by programming the USEPWMDIV bit, bit 20, in the **Run-Mode Clock Configuration (RCC)** (page 310) register at system control offset 0x060.

The PWMDIV bit field specifies the divisor of the system clock that is used to create the PWM clock.

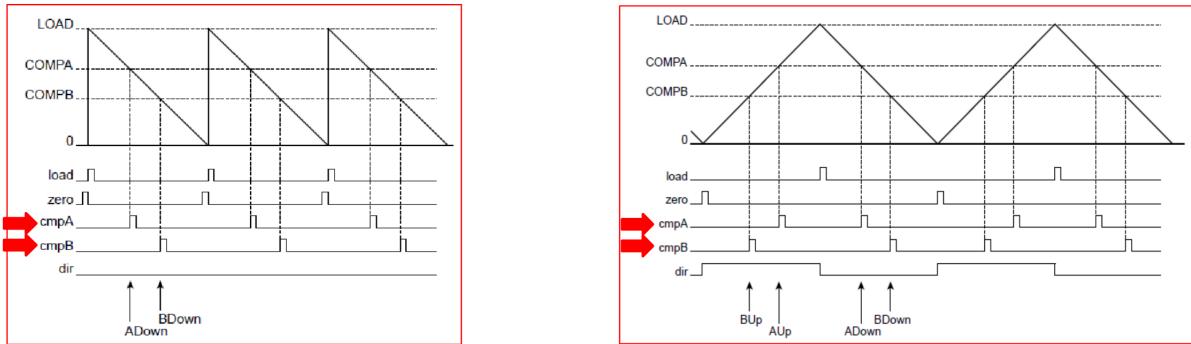

23.6 PWM generator timer

- Count-down mode: The timer starts from a digital value (called the load value) and decrements continuously to zero. Then, it is reset to the load value and is decremented continuously to zero again.
- Count-up/down mode: The timer starts from zero and increments continuously to a digital value (called the load value), and then decrements continuously to zero, and the process repeats.
- There are 3 different types of pulses, zero pulses, direction pulses and load pulses.

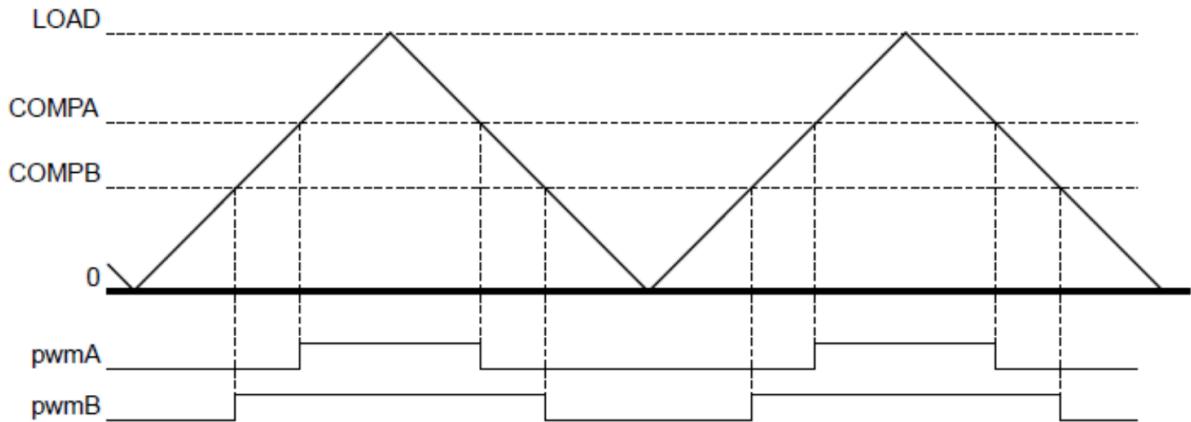

23.7 PWM generator comparators

- Each PWM generator has two digital comparators.
- One digital comparator holds the match value COMPA.
- Another digital comparator holds the match value COMPB.
- When the timer's count reaches one of these two match values, a high pulse is produced.

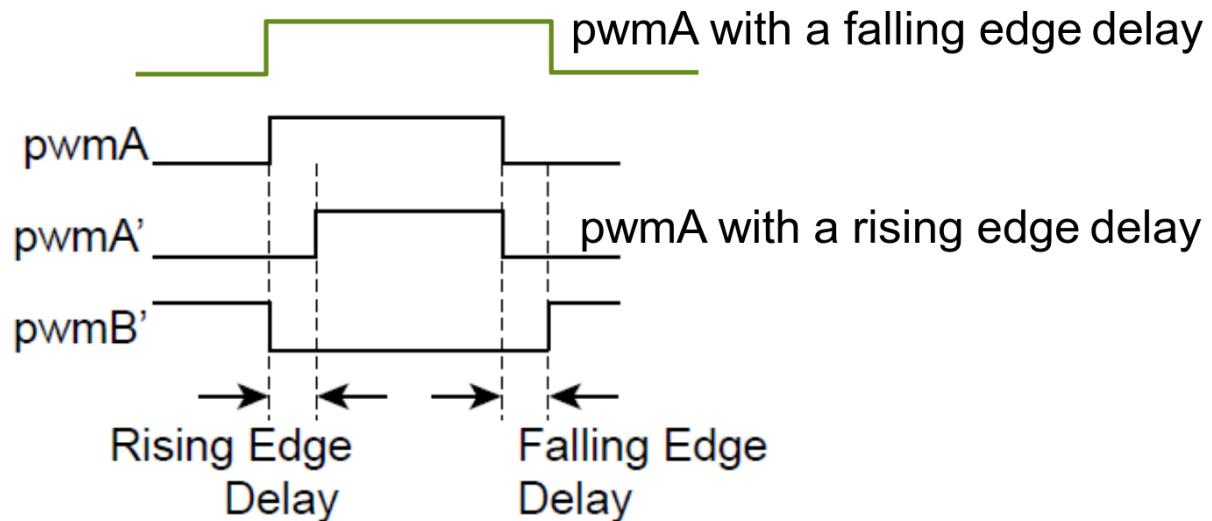

23.8 PWM signal generator

- The PWM generator has 5 internal pulses: load pulses, zero pulses, direction pulses, COMPA pulses, and COMPB pulses.
- The signal generator takes these pulses and produces two PWM waves: pwmA and pwmB.

23.9 PWM dead-band generator

- The dead-band generator gets inputs pwmA and pwmB from the signal generator and produces outputs pwmA' and pwmB'.
- pwmA' is the version of pwmA with a rising edge delay.
- pwmB' is the inverted version of pwmA with a falling edge delay.

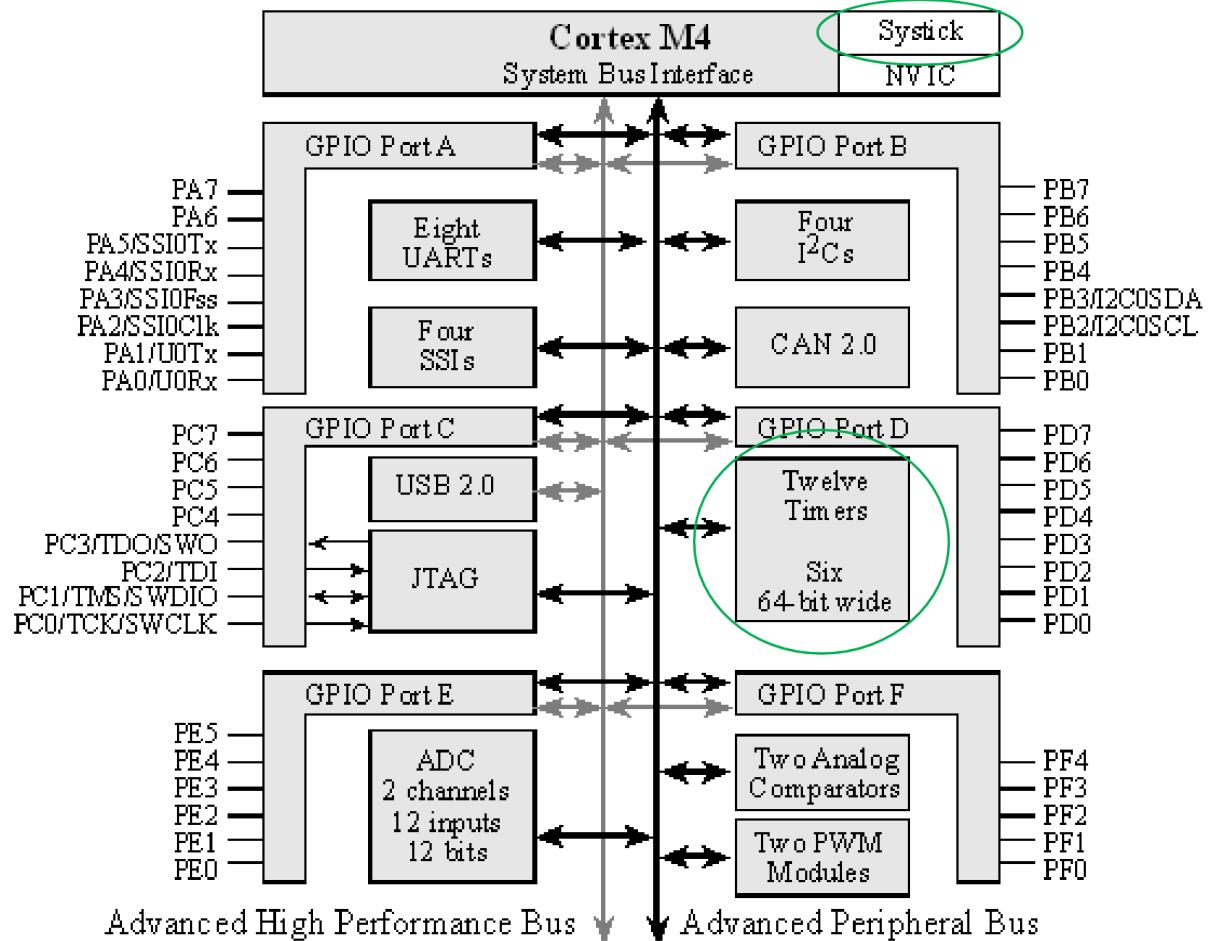

23.10 Initialisation and configuration

Initialise PWM generator 0 with a 25 kHz frequency, a 25% duty cycle on the MnPWM0 pin, and a 75% duty cycle on the MnPWM1 pin. The system clock is 20 MHz.

1. Enable the PWM clock by writing a value of 0x0010.0000 to the **RCGC0** ([page 317](#)) register in the system control module.
2. Enable the clock to the appropriate module via the **RCGC2** ([page 320](#)) register in the system control module.
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** ([page 148](#)) register. To determine which GPIOs to configure, see [page 305](#).
4. Configure the PMCn fields in the **GPIOPCTL** ([page 158](#)) register to assign the PWM signals to the appropriate pins. See [page 130](#) and [page 158](#).
5. Configure the **Run-Mode Clock Configuration (RCC)** ([page 310](#)) register in the system control module to use the PWM divide (USEPWMDIV) and set the divider (PWMDIV) to divide by 2 (0x00).
6. Configure the PWM generator for count-down mode with immediate updates to the parameters.
 - Write 0x0000.0000 (reset) to the **PWM0CTL** ([page 322](#)) register.
 - Write 0x0000.008C to the **PWM0GENA** ([page 328](#)) register.
 - Write 0x0000.080C to the **PWM0GENB** ([page 330](#)) register.
7. Set the period.
 - For a 25 kHz frequency, each period is $\frac{1}{25,000}$ or 40 μ s.
 - The PWM clock source is 10 MHz, which is the system clock, 20 MHz, divided by 2. 10 MHz is 10 clock ticks, or 1 μ s. Hence, 40 μ s is 400 clock ticks.
 - Use this value to set the **PWM0LOAD** ([page 332](#)) register. In count-down mode, set the LOAD field in the **PWM0LOAD** ([page 332](#)) register to the requested period minus 1.
 - Hence, write 0x0000.018F (399) to the **PWM0LOAD** ([page 332](#)) register.
8. Set the pulse width of the MnPWM0 pin for a 25% duty cycle.
 - Write 0x0000.012B (299) to the **PWM0CMPA** ([page 333](#)) register.
9. Set the pulse width of the MnPWM1 pin for a 75% duty cycle.
 - Write 0x0000.0063 (99) to the **PWM0CMPB** ([page 334](#)) register.
10. Start the timers in PWM generator 0.
 - Write 0x0000.0001 (enable bit 0) to the **PWM0CTL** ([page 322](#)) register.
11. Enable PWM outputs.
 - Write 0x0000.0003 to the **PWMENABLE** ([page 335](#)) register.

24 TM4C123GH6PM timers and counters

24.1 System timer (SysTick)

The Cortex-m4 has an integrated 24-bit system timer (SysTick) running on the bus clock frequency.

SysTick features:

- 24-bit clear-on write
- Decrementing
- Wrap-on-zero counter with flexible control mechanism

The SysTick can be used as a **timer** in several different ways:

- A **real time operating system (RTOS) tick timer** that fires at a programmable rate, like at 100 Hz for example, and invokes a SysTick routine.
- A **high-speed alarm timer** using the system clock.
- A **variable rate alarm or signal timer**. The duration is range-dependent on the reference clock used and the dynamic range of the counter.

The SysTick can be used as a **counter** in the following ways:

- A **simple counter** used to measure time to completion and time taken.
- An **internal clock source** control based on missing or meeting durations.
- The COUNT bit in the **STCTRL** (page 395) control and status register can be used to determine if an action completed with a set duration.

24.1.1 Register map

Base: 0xE000.E000

Offset	Name	Type	Reset	Description
System Timer (SysTick) Registers				
0x010	STCTRL	RW	0x0000.0004	SysTick Control and Status Register
0x014	STRELOAD	RW	-	SysTick Reload Value Register
0x018	STCURRENT	RWC	-	SysTick Current Value Register

24.1.2 Registers

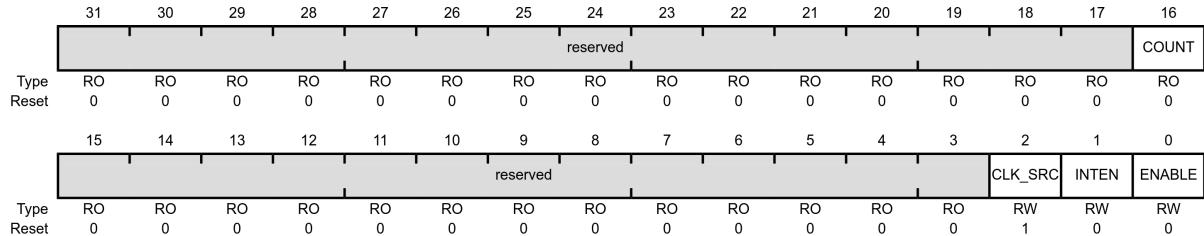

The timer consists of 3 registers:

1. SysTick Control and Status (STCTRL) ([page 395](#))
 - Control the status counter to configure its clock.
 - Enable the counter.
 - Enable the SysTick interrupt.
 - Determine the counter status.
2. SysTick Reload Value (STRELOAD) ([page 397](#))
 - Reload the value for the counter.
 - Provide the counter's wrap value.
3. SysTick Current Value (STCURRENT) ([page 398](#))
 - The current value of the counter.

24.1.2.1 SysTick Control and Status Register (STCTRL)

Note: This register can only be accessed from privileged mode.

- Base 0xE000.E000
- Offset 0x010
- Type RW, reset 0x0000.0004

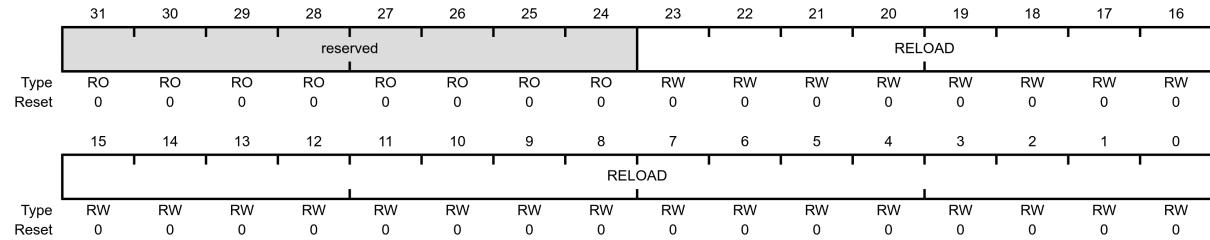

Bit/Field	Name	Type	Reset	Description

Value	Description									
0	The counter is disabled.									
1	Enables SysTick to operate in a multi-shot way. That is, the counter loads the RELOAD value and begins counting down. On reaching 0, the COUNT bit is set and an interrupt is generated if enabled by INTEN. The counter then loads the RELOAD value again and begins counting.									

24.1.2.2 SysTick Reload Value Register (STRELOAD)

Note: This register can only be accessed from privileged mode.

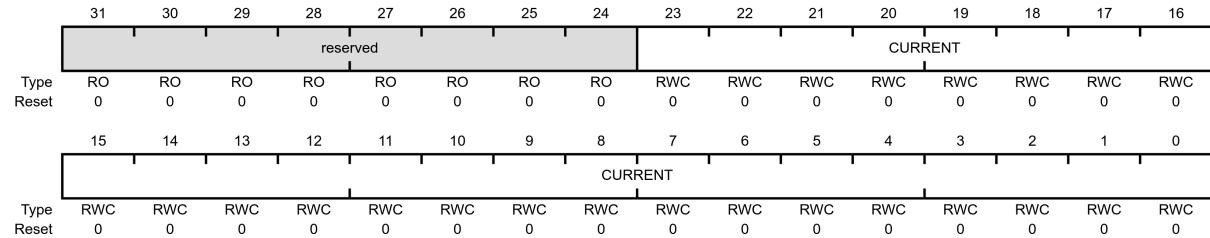

- Base 0xE000.E000
- Offset 0x014
- Type RW, reset -

Bit/Field	Name	Type	Reset	Description
31:24	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
23:0	RELOAD	RW	0x00.0000	Reload Value Value to load into the SysTick Current Value (STCURRENT) (page 398) register when the counter reaches 0.

24.1.2.3 SysTick Current Value Register (STCURRENT)

- Base 0xE000.E000
- Offset 0x018
- Type RWC, reset -

Bit/Field	Name	Type	Reset	Description
31:24	reserved	RO	0x00	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
23:0	CURRENT	RWC	0x00.0000	<p>Current Value</p> <p>This field contains the current value at the time the register is accessed. No read-modify-write protection is provided, so change with care.</p> <p>This register is write-clear. Writing to it with any value clears the register. Clearing this register also clears the COUNT bit of the STCTRL (page 395) register.</p>

24.1.3 Initialisation sequence

1. Clear the **ENABLE** bit, which is bit 0 of the **STCTRL** (page 395) register, to turn off the SysTick during initialisation.
2. Program the value in the **STRELOAD** (page 397) register to a value that is **1 bit less** than the actual value required.

For example, for a 80 MHz clock, the value of 800,000 is 10 ms.

3. Clear the **STCURRENT** (page 398) register by writing to it with any value.
4. Configure the **STCTRL** (page 395) register for the required operation.
 - Set **CLK_SRC** (bit 2) to 1 to use the system clock.
 - Clear **INTEN** (bit 1) if interrupt is not needed.
 - Set **ENABLE** (bit 0) to 1 to turn on the SysTick timer.

Note: When the processor is halted for debugging, the counter does not decrement.

- When SysTick timer is enabled, the timer counts down on each clock from the **STRELOAD** (page 397) value to zero.
- Reloads (wraps) to the value in the **STRELOAD** (page 397) register on the next clock edge.
- Clearing the **STRELOAD** (page 397) register disables the counter on the next wrap.
- When the timer reaches zero, the **COUNT** status (bit 16) in the **STCTRL** (page 395) register is set. The **COUNT** bit clears on reads.
- On the next clock cycle, the **STCURRENT** (page 398) register is loaded with the **STRELOAD** (page 397) value again.
- Writing to the **STCURRENT** (page 398) register clears the register and the **COUNT** status bit.
- On a read, the current value is the value of the register at the time the register is accessed.

24.1.3.1 Example code

```
STCTRL      EQU 0xE000E010      ; STCTRL register address
STRELOAD    EQU 0xE000E014      ; STRELOAD register address

24.2 General purpose timers (GPTM)

- These are different timers to SysTick.
- Input capture mode to make time measurements of input signals.
- Input capture to measure period or pulse width of digital signals.
- Use to trigger interrupts on rising or falling edges of external signals.
- Programmable timers can be used to count or time external events that drive the Timer input pins.
- Timers can be used to trigger analogue-to-digital conversions (ADC) when a time-out occurs in periodic and one-shot mode.
- The general-purpose timer module (GPTM) contains six 16/32-bit GPTM blocks and six 32/64-bit wide GPTM blocks.
- Count up or down.
- Twelve 16/32-bit Capture Compare PWM pins (CCP).
- Twelve 32/64-bit Capture Compare PWM pins (CCP).
- Daisy chaining of timer modules to allow a single timer to initiate multiple timing events.
- Timer synchronisation allows selected timers to start counting on the same clock cycle.
- ADC event trigger.
- User-enabled stalling when the microcontroller asserts CPU Halt flag during debug (excluding RTC mode).
- Ability to determine the elapsed time between the assertion of the timer interrupt and entry into the interrupt service routine.
- Efficient transfers using Micro Direct Memory Access Controller (μ DMA)
 - Dedicated channel for each timer.
 - Burst request generated on timer interrupt.

Each block has the following functional options:

- 16/32-bit operating modes:
 - 16 or 32-bit programmable one-shot timers.
 - 16 or 32-bit programmable periodic timer.
 - 16-bit general-purpose timer with an 8-bit prescaler.
 - 32-bit Real-Time Clock (RTC) when using an external 32.768 kHz clock as the input.
 - 16-bit input-edge count or time-capture modes with an 8-bit prescaler.
 - 16-bit PWM mode with an 8-bit prescaler and software-programmable output inversion of the PWM signal.
- 32/64-bit operating modes:
 - 32 or 64-bit programmable one-shot timer.
 - 32 or 64-bit programmable periodic timer.
 - 32-bit general-purpose timer with an 16-bit prescaler.
 - 64-bit Real-Time Clock (RTC) when using an external 32.768 kHz clock as the input.
 - 32-bit input-edge count or time-capture modes with a 16-bit prescaler.
 - 32-bit PWM mode with a 16-bit prescaler and software-programmable output inversion of the PWM signal.

24.2.1 Block diagram

24.2.2 Input capture pins

Input capture pins are T_nCCP0 or T_nCCP1.

Timer	Up/Down Counter	Even CCP Pin	Odd CCP Pin
16/32-Bit Timer 0	Timer A	T0CCP0	-
	Timer B	-	T0CCP1
16/32-Bit Timer 1	Timer A	T1CCP0	-
	Timer B	-	T1CCP1
16/32-Bit Timer 2	Timer A	T2CCP0	-
	Timer B	-	T2CCP1
16/32-Bit Timer 3	Timer A	T3CCP0	-
	Timer B	-	T3CCP1
16/32-Bit Timer 4	Timer A	T4CCP0	-
	Timer B	-	T4CCP1
16/32-Bit Timer 5	Timer A	T5CCP0	-
	Timer B	-	T5CCP1
32/64-Bit Wide Timer 0	Timer A	WT0CCP0	-
	Timer B	-	WT0CCP1
32/64-Bit Wide Timer 1	Timer A	WT1CCP0	-
	Timer B	-	WT1CCP1
32/64-Bit Wide Timer 2	Timer A	WT2CCP0	-
	Timer B	-	WT2CCP1
32/64-Bit Wide Timer 3	Timer A	WT3CCP0	-
	Timer B	-	WT3CCP1
32/64-Bit Wide Timer 4	Timer A	WT4CCP0	-
	Timer B	-	WT4CCP1
32/64-Bit Wide Timer 5	Timer A	WT5CCP0	-
	Timer B	-	WT5CCP1

For input capture, an external signal is connected to an input, either T_nCCP0 or T_nCCP1. Three different input capture applications are:

- Interrupt service routine (ISR) is executed on the active edge of an external signal.
- Perform two rising edge input captures and subtract the two to get the **period**.
- Perform a rising edge and then a falling edge capture and subtract the two measurements to get the **pulse width**.

24.2.3 Functional description

- Each GPTM block are two free-running up/down counters, referred to as Timer A and Timer B, controlled by the **GPTMTAV** (page 419).
- Two prescaler registers **GPTMTAPR** (page 420).
- Two match registers **GPTMTAMATCHR** (page 421).
- Two prescaler match registers **GPTMTAPMR** (page 422).
- 16-bit counters have a 16-bit counting range and can be joined together to provide a 32-bit counting range.
- 32-bit counters have a 32-bit counting range and can be joined together to provide a 64-bit counting range.

24.2.4 Timer modes

Mode	Timer Use	Count Direction	Counter Size		Prescaler Size ^a		Prescaler Behavior (Count Direction)
			16/32-bit GPTM	32/64-bit Wide GPTM	16/32-bit GPTM	32/64-bit Wide GPTM	
One-shot	Individual	Up or Down	16-bit	32-bit	8-bit	16-bit	Timer Extension (Up), Prescaler (Down)
	Concatenated	Up or Down	32-bit	64-bit	-	-	N/A
Periodic	Individual	Up or Down	16-bit	32-bit	8-bit	16-bit	Timer Extension (Up), Prescaler (Down)
	Concatenated	Up or Down	32-bit	64-bit	-	-	N/A
RTC	Concatenated	Up	32-bit	64-bit	-	-	N/A
Edge Count	Individual	Up or Down	16-bit	32-bit	8-bit	16-bit	Timer Extension (Both)
Edge Time	Individual	Up or Down	16-bit	32-bit	8-bit	16-bit	Timer Extension (Both)
PWM	Individual	Down	16-bit	32-bit	8-bit	16-bit	Timer Extension

a. The prescaler is only available when the timers are used individually.

24.2.7 Essential function in registers

- External input pins (CCP0, CCP1)
- Trigger flag bit [Raw Interrupt Status] (CAERIS)
- Two edge control bits (positive, negative, both edges) or event mode (TAEVENT)
- Interrupt Mask (CAEIM)
- 16/32-bit capture register (TAR, TBR)

24.2.8 Overview of GPTM use

- An external signal is connected to input capture pin.
- Specify whether input capture event will trigger on rising or falling edge during initialisation.
- The timer counts down from the 16-bit integer limit. When it hits zero, it rolls over back to 0xFFFF and continues counting down.
- When an input capture event happens, the current timer value is copied into the input capture register (TAR, TBR).
- The input capture flag is set (CAERIS).
- An interrupt is requested if armed (CAEIM).

24.2.9 Prescaler configurations

Prescale (8-bit value)	Number of Timer Clocks (Tc ^a)	Max Time	Units
00000000	1	0.8192	ms
00000001	2	1.6384	ms
00000010	3	2.4576	ms
-----	-	-	-
11111101	254	208.0768	ms
11111110	255	208.896	ms
11111111	256	209.7152	ms

a. Tc is the clock period.

Table 1: 16-bit Timer with Prescaler Configurations

Prescale (16-bit value)	Number of Timer Clocks (Tc ^a)	Max Time	Units
0x0000	1	53.687	s
0x0001	2	107.374	s
0x0002	3	214.748	s
-----	-	-	-
0xFFFFD	65534	0.879	10 ⁶ s
0xFFFFE	65535	1.759	10 ⁶ s
0xFFFF	65536	3.518	10 ⁶ s

a. Tc is the clock period.

Value	Description									
0	A Timer A Time-Out interrupt has not occurred or is masked.									
1	An unmasked Timer A Time-Out interrupt has occurred.									

24.2.11 Initialisation and configuration

1. To use a GPTM, the appropriate TIMERn bit must be set in the **RCGCTIMER** ([page 440](#)) or **RCGCWTIMER** ([page 442](#)) register.
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** ([page 133](#)) register.
3. Configure the PMCn fields in the **GPIOPCTL** ([page 158](#)) register to assign the CCP signals to the appropriate pins ([page 130](#)).

24.2.11.1 One-shot or periodic timer configuration

1. Ensure the timer is disabled, which means to ensure that the TnEN bit in the **GPTMCTL** ([page 409](#)) register is cleared before making any changes.
2. Write 0x0000.0000 to the **GPTM Configuration (GPTMCFG)** ([page 407](#)) register.
3. Configure the TnMR field in the **GPTM Timer n Mode (GPTMTnMR)** ([page 414](#)) register:
 - a. Write a value of 0x1 for One-Shot mode.
 - b. Write a value of 0x2 for Periodic mode.
4. Configure the TnSNAPS, TnWOT, TnMIE, and TnCDIR bits in the **GPTMTnMR** ([page 414](#)) register.
5. Load the start value into the **GPTM Timer n Interval Load (GPTMTnILR)** ([page 423](#)) register.
6. If interrupts are required, set the appropriate bits in the **GPTM Interrupt Mask (GPTMIMR)** ([page 446](#)).
7. Set the TnEN bit in the **GPTMCTL** ([page 409](#)) register to enable the timer and start counting.
8. Poll the **GPTMRIS** ([page 449](#)) register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the appropriate bit of the **GPTM Interrupt Clear (GPTMICR)** ([page 444](#)) register.

In One-Shot mode, the timer stops counting after the time-out event. To re-enable the timer, repeat the sequence.

24.2.11.2 Real time clock mode

1. Ensure the timer is disabled, which means the TnEN bit is cleared, before making any changes.
2. If the timer has been operating in a different mode prior to this, clear any residual set bits in the **GPTM Timer n Mode (GPTMTnMR)** ([page 414](#)) register before reconfiguring.
3. Write 0x0000.0001 to the **GPTM Configuration Register (GPTMCFG)** ([page 407](#)) register.
4. Write the match value to the **GPTM Timer n Match (GPTMTnMATCHR)** ([page 421](#)) register.
5. Set or clear the RTCEN and TnSTALL bit in the **GPTM Control (GPTMCTL)** ([page 409](#)) register as needed.
6. If interrupts are required, set the RTCIM bit in the **GPTM Interrupt Mask (GPTMIMR)** ([page 446](#)) register.
7. Set the TAEN bit in the **GPTMCTL** ([page 409](#)) register to enable the timer and start counting.

When the timer count equals the value in the **GPTMTnMATCHR** ([page 421](#)) register, the GPTM asserts the RTCRIS bit in the **GPTMRIS** ([page 449](#)) register and continues counting until Timer A is disabled or a hardware reset occurs.

The interrupt is cleared by writing to the RTCCINT bit in the **GPTMICR** ([page 444](#)) register.

Note that if the **GPTMTnILR** ([page 423](#)) register is loaded with a new value, the timer begins counting at this new value and continues until it reaches 0xFFFF.FFFF, at which point it rolls over.

24.2.11.3 Input Edge Count mode

A timer is configured to the Input Edge Count mode by the follow sequence:

1. Ensure the timer is disabled, which means the TnEN bit is cleared, before making any changes.
2. Write 0x0000.0004 to the **GPTM Configuration (GPTMCFG)** (page 407) register.
3. In the **GPTM Timer n Mode (GPTMTnMR)** (page 414) register, write 0x0 to the TnCMR field and the 0x3 to the TnMR field.
4. Configure the type of events that the timer captures by writing to the TnEVENT field of the **GPTM Control (GPTMCTL)** (page 409) register.
5. Program registers according to the count direction:
 - In down-count mode, the **GPTMTnMATCHR** (page 421) and **GPTMTnPMR** (page 422) registers are configured so that the difference between the value in the **GPTMTnILR** (page 423) and the **GPTMTnPR** (page 420) registers and the **GPTMTnMATCHR** (page 421) and **GPTMTnPMR** (page 422) equals the number of edge events that must be counted.
 - In up-count mode, the timer counts from 0x0 to the value in the **GPTMTnMATCHR** (page 421) and **GPTMTnPMR** (page 422) registers. Note that when executing an up-count, the value of the **GPTMTnPR** (page 420) and **GPTMTnILR** (page 423) must be greater than the value of **GPTMTnPMR** (page 422) and **GPTMTnMATCHR** (page 421).
6. If interrupts are required, set the CnMIM bit in the **GPTM Interrupt Mask (GPTMIMR)** (page 446) register.
7. Set the TnEN bit in the **GPTMCTL** (page 409) register to enable the timer and begin waiting for edge events.
8. Poll the CnMRIS bit in the **GPTMRIS** (page 449) register or wait for the interrupt to be generated if enabled.

In both cases, the status flags are cleared by writing a 1 to the CnMCINT bit of the **GPTM Interrupt Clear (GPTMICR)** (page 444) register.

When counting down in Input Edge Count mode, the timer stops after the programmed number of edge events has been detected. To re-enable the timer, ensure that the TnEN bit is cleared and repeat steps 4 through 8.

24.2.11.4 Input Edge Time mode

A timer is configured to Input Edge Time mode by the following sequence:

1. Ensure the timer is disabled, which means the TnEN bit is cleared, before making any changes.
2. Write 0x0000.0004 to the **GPTM Configuration (GPTMCFG)** ([page 407](#)) register.
3. In the **GPTM Timer Mode (GPTMTnMR)** ([page 414](#)) register, write 0x1 to the TnCMR field and 0x3 to the TnMR field and select a count direction by programming the TnCDIR bit.
4. Configure the type of event that the timer captures by writing to the TnEVENT field of the **GPTM Control (GPTMCTL)** ([page 409](#)) register.
5. If a prescaler is to be used, write the prescale value to the **GPTM Timer n Interval Load (GPTMTnPR)** ([page 420](#)) register.
6. Load the timer start value into the **GPTM Timer n Interval Load (GPTMTnILR)** ([page 423](#)) register.
7. If interrupts are required, set the CnEIM bit in the **GPTM Interrupt Mask (GPTMIMR)** ([page 446](#)) register.
8. Set the TnEN bit in the **GPTM Control (GPTMCTL)** ([page 409](#)) register to enable the timer and start counting.
9. Poll the CnERIS bit in the **GPTMRIS** ([page 449](#)) register or wait for the interrupt to be generated (if enabled).

In both cases, the status flags are cleared by writing a 1 to the CnECINT bit of the **GPTM Interrupt Clear (GPTMICR)** ([page 444](#)) register. The time at which the event happened can be obtained by reading the **GPTM Timer n (GPTMTnR)** ([page 424](#)) register.

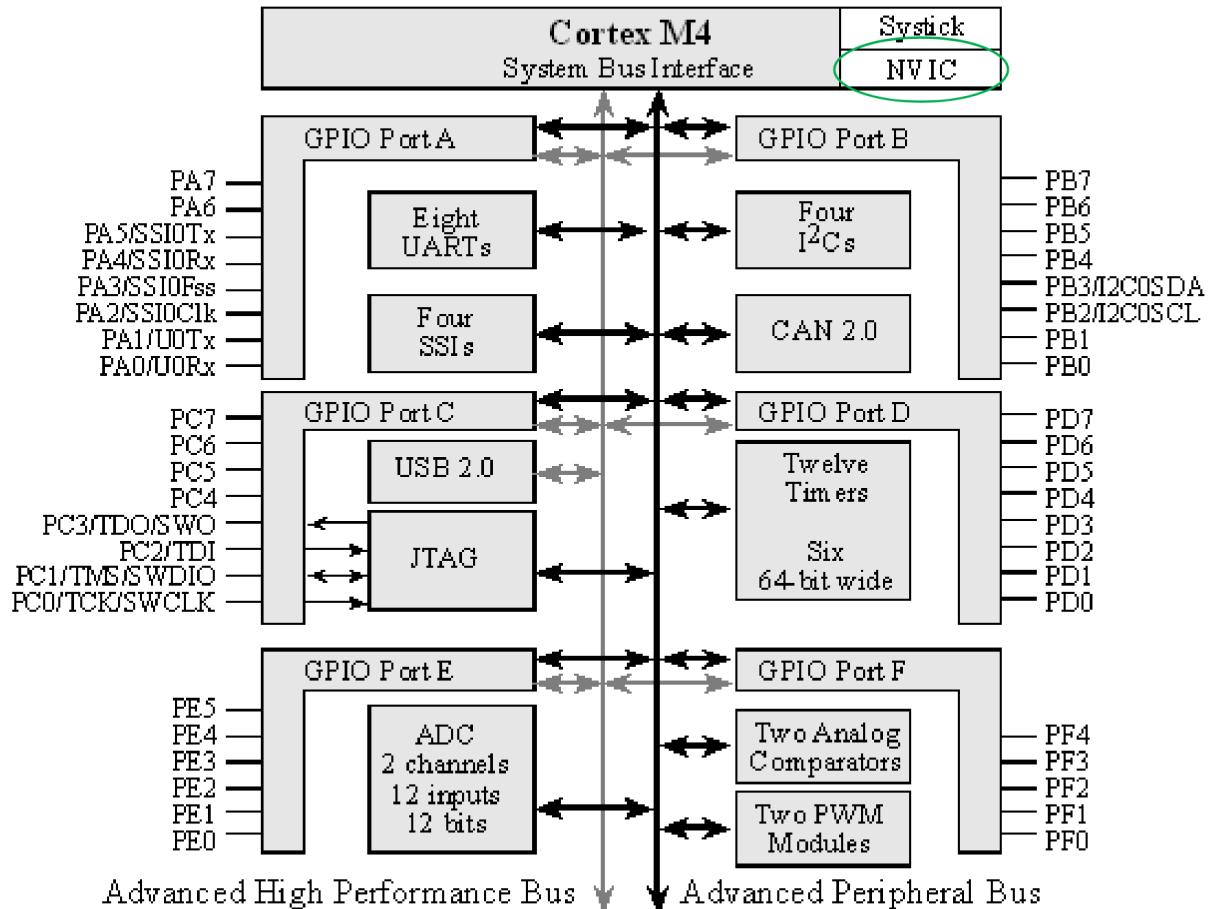

24.2.11.5 PWM mode

A timer is configured to PWM mode using the following sequence:

1. Ensure the timer is disabled, which means the TnEN bit is cleared, before making any changes.
2. Write 0x0000.0004 to the **GPTM Configuration (GPTMCFG)** ([page 407](#)) register.
3. In the **GPTM Timer n Mode (GPTMTnMR)** ([page 414](#)) register, set the TnAMS bit to 0x1, the TnCMR bit to 0x0, and the TnMR field to 0x2.
4. Configure the output state of the PWM signal, like whether or not it is inverted, in the TnPWML field of the **GPTM Control (GPTMCTL)** ([page 409](#)) register.
5. If a prescaler is to be used, write the prescale value to the **GPTM Timer n Prescale (GPTMTnPR)** ([page 420](#)) register.
6. If PWM interrupts are used, configure the interrupt condition in the TnEVENT field in the **GPTMCTL** ([page 409](#)) register and enable the interrupts by setting the TnPWMIE bit in the **GPTMTnMR** ([page 414](#)) register. Note that the edge detection interrupt behaviour is reversed when the PWM output is inverted.
7. Load the timer start value into the **GPTM Timer n Interval Load (GPTMTnILR)** ([page 423](#)) register.
8. Load the **GPTM Timer n Match (GPTMTnMATCHR)** ([page 421](#)) register with the match value.
9. Set the TnEN bit in the **GPTM Control (GPTMCTL)** ([page 409](#)) register to enable the timer and begin generation of the output PWM signal.

In PWM time mode, the timer continues running after the PWM signal has been generated. The PWM period can be adjusted at any time by writing to the **GPTMTnILR** ([page 423](#)) register, and the change takes effect on the next cycle after the write.

25 TM4C123GH6PM interrupts

- Controlled by the Nested Vectored Interrupt Controller (NVIC).
- Interrupt Request (IRQ) is an exception signaled by a peripheral or generated by a software request and fed through the NVIC. The latter is prioritised.
- All interrupts are asynchronous to instruction execution.
- In the system, peripherals use interrupts to communicate with the processor.

25.1 Interrupts

Vector Number	Interrupt Number (Bit in Interrupt Registers)	Vector Address or Offset	Description
0-15	-	0x0000.0000 - 0x0000.003C	Processor exceptions
16	0	0x0000.0040	GPIO Port A

25.2 Registers

25.2.1 Interrupt 0-31 Set Enable (EN0)

- Base 0xE000.E000
- Offset 0x100
- Type RW, reset 0x0000.0000

Registers:

- Register 4: Interrupt 0-31 Set Enable (EN0), offset 0x100
- Register 5: Interrupt 32-63 Set Enable (EN1), offset 0x104
- Register 6: Interrupt 64-95 Set Enable (EN2), offset 0x108
- Register 7: Interrupt 96-127 Set Enable (EN3), offset 0x10C

Note: This register can only be accessed from privileged mode.

On a write, no effect.	1	On a read, indicates the interrupt is enabled. On a write, clears the corresponding INT[n] bit in the EN4 (page 465) register, disabling interrupt [n].
Value	Description									
0	On a read, indicates the interrupt is disabled. On a write, no effect.									
1	On a read, indicates the interrupt is enabled. On a write, clears the corresponding INT[n] bit in the EN4 (page 465) register, disabling interrupt [n].									

25.2.5 Interrupt 0-3 Priority (PRI0)

- Base 0xE000.E000
- Offset 0x400
- Type RW, reset 0x0000.0000

Registers:

- Register 29: Interrupt 0-3 Priority (PRI0), offset 0x400
- Register 30: Interrupt 4-7 Priority (PRI1), offset 0x404
- Register 31: Interrupt 8-11 Priority (PRI2), offset 0x408
- Register 32: Interrupt 12-15 Priority (PRI3), offset 0x40C
- Register 33: Interrupt 16-19 Priority (PRI4), offset 0x410
- Register 34: Interrupt 20-23 Priority (PRI5), offset 0x414
- Register 35: Interrupt 24-27 Priority (PRI6), offset 0x418
- Register 36: Interrupt 28-31 Priority (PRI7), offset 0x41C
- Register 37: Interrupt 32-35 Priority (PRI8), offset 0x420
- Register 38: Interrupt 36-39 Priority (PRI9), offset 0x424
- Register 39: Interrupt 40-43 Priority (PRI10), offset 0x428
- Register 40: Interrupt 44-47 Priority (PRI11), offset 0x42C
- Register 41: Interrupt 48-51 Priority (PRI12), offset 0x430
- Register 42: Interrupt 52-55 Priority (PRI13), offset 0x434
- Register 43: Interrupt 56-59 Priority (PRI14), offset 0x438
- Register 44: Interrupt 60-63 Priority (PRI15), offset 0x43C
- Register 45: Interrupt 64-67 Priority (PRI16), offset 0x440
- Register 46: Interrupt 68-71 Priority (PRI17), offset 0x444
- Register 47: Interrupt 72-75 Priority (PRI18), offset 0x448
- Register 48: Interrupt 76-79 Priority (PRI19), offset 0x44C
- Register 49: Interrupt 80-83 Priority (PRI20), offset 0x450
- Register 50: Interrupt 84-87 Priority (PRI21), offset 0x454
- Register 51: Interrupt 88-91 Priority (PRI22), offset 0x458
- Register 52: Interrupt 92-95 Priority (PRI23), offset 0x45C
- Register 53: Interrupt 96-99 Priority (PRI24), offset 0x460
- Register 54: Interrupt 100-103 Priority (PRI25), offset 0x464
- Register 55: Interrupt 104-107 Priority (PRI26), offset 0x468
- Register 56: Interrupt 108-111 Priority (PRI27), offset 0x46C
- Register 57: Interrupt 112-115 Priority (PRI28), offset 0x470
- Register 58: Interrupt 116-119 Priority (PRI29), offset 0x474
- Register 59: Interrupt 120-123 Priority (PRI30), offset 0x478
- Register 60: Interrupt 124-127 Priority (PRI31), offset 0x47C
- Register 61: Interrupt 128-131 Priority (PRI32), offset 0x480
- Register 62: Interrupt 132-135 Priority (PRI33), offset 0x484
- Register 63: Interrupt 136-138 Priority (PRI34), offset 0x488

Note: This register can only be accessed from privileged mode.

The **PRIn** (page 468) registers provide 3-bit priority fields for each interrupt. These registers are byte accessible. Each register holds four priority fields that are assigned to interrupts as follows:

PRIn Register Bit Field	Interrupt
Bits 31:29 (INTD)	Interrupt [4n+3]
Bits 23:21 (INTC)	Interrupt [4n+2]
Bits 15:13 (INTB)	Interrupt [4n+1]
Bits 7:5 (INTA)	Interrupt [4n]

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Type				INTB			reserved			INTA			reserved			
Reset	RW	RW	RW	RO	RO	RO	RO	RO	RW	RW	RW	RO	RO	RO	RO	RO
	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit/Field	Name	Type	Reset	Description
31:29	INTD	RW	0x0	Interrupt Priority for Interrupt [4n+3] This field holds a priority value, 0-7, for the interrupt with the number [4n+3], where n is the number of the Interrupt Priority register (n=0 for PRI0 (page 468), and so on). The lower the value, the greater the priority of the corresponding interrupt.
28:24	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
23:21	INTC	RW	0x0	Interrupt Priority for Interrupt [4n+2] This field holds a priority value, 0-7, for the interrupt with the number [4n+2], where n is the number of the Interrupt Priority register (n=0 for PRI0 (page 468), and so on). The lower the value, the greater the priority of the corresponding interrupt.
20:16	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
15:13	INTB	RW	0x0	Interrupt Priority for Interrupt [4n+1] This field holds a priority value, 0-7, for the interrupt with the number [4n+1], where n is the number of the Interrupt Priority register (n=0 for PRI0 (page 468), and so on). The lower the value, the greater the priority of the corresponding interrupt.

Bit/Field	Name	Type	Reset	Description
12:8	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:5	INTA	RW	0x0	<p>Interrupt Priority for Interrupt [4n]</p> <p>This field holds a priority value, 0-7, for the interrupt with the number [4n], where n is the number of the Interrupt Priority register (n=0 for PRI0 (page 468), and so on). The lower the value, the greater the priority of the corresponding interrupt.</p>
4:0	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

25.2.6 System Handler Priority 3 (SYSPRI3)

- Base 0xE000.E000
- Offset 0xD20
- Type RW, reset 0x0000.0000

Bit/Field	Name	Type	Reset	Description
31:29	TICK	RW	0x0	SysTick Exception Priority This field configures the priority level of the SysTick exception. Configurable priority values are in the range 0-7, with lower values having higher priority.
28:24	reserved	RO	0x0	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
23:21	PENDSV	RW	0x0	PendSV Priority This field configures the priority level of PendSV. Configurable priority values are in the range 0-7, with lower values having higher priority.
20:8	reserved	RO	0x000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.
7:5	DEBUG	RW	0x0	Debug Priority This field configures the priority level of Debug. Configurable priority values are in the range 0-7, with lower values having higher priority.
4:0	reserved	RO	0x0000	Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.

25.3 Working with interrupts

- There are 5 sets of enable (**EN_n** (page 464)) registers on the TM4C123GH6PM.
- They enable the interrupts and show which interrupts are enabled.
- Base: 0xE000.E000
 - Interrupt 0-31 Set Enable (EN0) (page 464), offset 0x100
 - Interrupt 32-63 Set Enable (EN1) (page 464), offset 0x104
 - Interrupt 64-95 Set Enable (EN2) (page 464), offset 0x108
 - Interrupt 96-127 Set Enable (EN3) (page 464), offset 0x10C
 - Interrupt 128-138 Set Enable (EN4) (page 465), offset 0x110
- Bit mappings for **EN_n** (page 464):
 - Bit 0 of **EN0** (page 464) corresponds to interrupt 0, and bit 31 corresponds to interrupt 31.
 - Bit 0 of **EN1** (page 464) corresponds to interrupt 32, and bit 31 corresponds to interrupt 63.
 - Bit 0 of **EN2** (page 464) corresponds to interrupt 64, and bit 31 corresponds to interrupt 95.
 - Bit 0 of **EN3** (page 464) corresponds to interrupt 96, and bit 31 corresponds to interrupt 127.
 - Bit 0 of **EN4** (page 465) corresponds to interrupt 128, and bit 10 corresponds to interrupt 138.
- If a pending interrupt is enabled, the NVIC activates the interrupt based on its priority.
- If an interrupt is not enabled, asserting its interrupt signal changes the interrupt state to pending, but the NVIC never activates the interrupt, regardless of its priority.
- To enable an interrupt, like SS1 (interrupt 34) for example.
 - Set bit 2 of **EN1** (page 464) to 1.
 - Note that **writing zeros** to the registers **EN0** (page 464) through **EN4** (page 465) **does not disable the interrupt**.
 - To disable the interrupt, write 1s to the corresponding **DIS0** (page 466) to **DIS4** (page 467) registers.
- Bit mappings for **DIS_n** (page 466):
 - Bit 0 of **DIS0** (page 466) corresponds to interrupt 0, and bit 31 corresponds to interrupt 31.
 - Bit 0 of **DIS1** (page 466) corresponds to interrupt 32, and bit 31 corresponds to interrupt 63.
 - Bit 0 of **DIS2** (page 466) corresponds to interrupt 64, and bit 31 corresponds to interrupt 95.
 - Bit 0 of **DIS3** (page 466) corresponds to interrupt 96, and bit 31 corresponds to interrupt 127.
 - Bit 0 of **DIS4** (page 467) corresponds to interrupt 128, and bit 10 corresponds to interrupt 138.

25.4 Interrupt priority

- There are 35 priority registers **PRIn** ([page 468](#)) on the TM4C123GH6PM.
- Each interrupt priority level can be specified by a 3-bit priority field giving a priority level of 0 to 7 for each interrupt. 0 is the highest priority, and 7 is the lowest priority.
- Each **PRIn** ([page 468](#)) register controls 4 priority fields. These 4 priority fields (INTA, INTB, INTC, and INTD) are assigned to interrupts as follows:

PRIn Register Bit Field	Interrupt
Bits 31:29 (INTD)	Interrupt [4n+3]
Bits 23:21 (INTC)	Interrupt [4n+2]
Bits 15:13 (INTB)	Interrupt [4n+1]
Bits 7:5 (INTA)	Interrupt [4n]

25.5 Initialising edge triggered interrupt on a pin

For example, making use of Port C bit 4 (PC4), interrupting on the rising edges:

1. Activate clock for Port C by writing 0x04 to the **RCGCGPIO** ([page 133](#)) register.
2. Enable PC4 by writing 0x10 to the **GPIODEN** ([page 135](#)) register.
3. Configure PC4 to be edge sensitive by writing 0x10 to the **GPIOIS** ([page 137](#)) register.
4. Configure PC4 to not interrupt on both edges by clearing the 0x10 bit in the **GPIOIBE** ([page 139](#)) register.
5. Configure PC4 to interrupt on the rising edge by writing 0x10 to the **GPIOIEV** ([page 138](#)) register.
6. Clear the interrupt on PC4 by writing 0x10 to the **GPIOICR** ([page 157](#)) register.
7. Turn on the interrupt on PC4 by writing 0x10 to the **GPIOIM** ([page 140](#)) register.
8. Set the interrupt priority of PC4 to 5 by writing 0x00A0.0000 to the **PRI0** ([page 468](#)) register to set bits 21 - 23.
9. Enable NVIC interrupt 2, which is the handler for Port C, by writing 0x04 to the **EN0** ([page 464](#)) register.

25.6 SysTick periodic interrupt

- The SysTick timer is a simple way to create periodic interrupts.
- A periodic interrupt is one that is generated on a fixed time basis.
- Useful when you need to do periodic polling.

The SysTick registers below are used to create a periodic interrupt.

Address	31-24	23-17	16	15-3	2	1	0	Name
\$E000E010	0	0	COUNT	0	CLK_SRC	INTEN	ENABLE	NVIC_ST_CTRL_R
\$E000E014	0			24-bit RELOAD value				NVIC_ST_RELOAD_R
\$E000E018	0			24-bit CURRENT value of SysTick counter				NVIC_ST_CURRENT_R

Address	31-29	28-24	23-21	20-8	7-5	4-0	Name
\$E000ED20	TICK	0	PENDSV	0	DEBUG	0	NVIC_SYS_PRI3_R

25.6.1 How to determine the frequency of the periodic interrupt

$$F_{\text{bus}} = \text{Frequency of the bus clock}$$

$$n = 24 \text{ bit reload value}$$

Hence the frequency of the periodic interrupt is $\frac{F_{\text{bus}}}{n+1}$.

25.6.2 SysTick periodic interrupt initialisation

- Clear the Enable bit in the **STCTRL** (page 395) register.
- Enter the 24 bit value into the **STRELOAD** (page 397) register.
- Write any value to the **STCURRENT** (page 398) register to clear the counter.
- Set **CLK_SRC** (bit 2) to 1 in the **STCTRL** (page 395) register.
- Enable **ITEN** to enable interrupts in the **STCTRL** (page 395) register.
- Set the priority level of the TICK interrupts (bits 29 - 31) on **SYSPRI3** (page 471) register.
- Set the Enable bit back in the **STCTRL** (page 395) register to turn on the counter.
- When the **CURRENT** value counts to 0, the **COUNT** flag is set.
- On the next clock, the **CURRENT** is loaded with the **RELOAD** value.
- If the **RELOAD** value is n, the **COUNT** flag will be configured to trigger an interrupt at every n+1 counts.

25.6.2.1 Example

- Activate the clock for Port D by writing 0x08 to the **RCGCGPIO** (page 133) register.
- Disable analogue mode for Port D by writing 0 to the **GPIOAMSEL** (page 152) register.
- Set Port D bit 0 (PD0) to output by writing 0x01 to the **GPIODIR** (page 136) register.
- Enable digital I/O on PD0 by writing 0x01 to the **GPIODEN** (page 135) register.
- Disable SysTick during setup by writing 0 to the **STCTRL** (page 395) register.
- Set the reload value by writing 0x00FFFF to the **STRELOAD** (page 397) register.
- Write any value, like a 0, to the **STCURRENT** (page 398) register to clear the register.
- Set **SYSPRI3** (page 471) register to priority 2 by writing 0x40000000 (bits 29 - 31) to it.
- Enable the core clock and interrupts by writing 0x00000007 to the **STCTRL** (page 395) register.

25.7 Timer period interrupt

To create a periodic interrupt:

- Set a prescale value, which can be any 8 bit number, loaded into the **GPTMTAPR** (page 420) register.
- Timer frequency = $\frac{\text{Bus frequency}}{\text{Prescale} + 1}$
- If using the default prescale of 0, then the timer frequency is equal to the bus frequency.
- Load the 32 bit counting value of the time, or the period, into the **GPTMTAILR** (page 423) register.

25.7.1 Initialisation

1. Enable the General Purpose Timer Module in the **RCGCTIMER** (page 440) register.
2. Clear the TAEN bit in the **GPTMCTL** (page 409) register to turn off the timer.
3. Write 0x00 to the **GPTMCFG** (page 407) register to set the timer to 32 bit mode.
4. Write 0x02 to the **GPTMTAMR** (page 414) register to configure for periodic mode.
5. Load the 32 bit PERIOD value into the **GPTMTAILR** (page 423) register.
6. Load PRESCALE into the **GPTMTAPR** (page 420) register.
7. Write a 1 to TAT0CINT in the **GPTMICR** (page 444) register to clear the time out flag.
8. Write a 1 to TATIM in the **GPTMIMR** (page 446) register to set the timeout interrupt.
9. Set the interrupt priority to the correct NVIC register.
10. Enable the correct interrupt in the NVIC interrupt enable register.
11. Set the TAEN bit back on to start the timer to begin counting down from the PERIOD value.

- The ARM's instruction format is a 4-byte instruction, consisting of the operation code (opcode), and the operands.
- Format 1: Opcode DestReg, Operand2
- Format 2: Opcode DestReg, SrcReg, Operand2
- Where:
 - Opcode is the operation code.
 - DestReg is the destination register to write the result to.
 - Operand2 is the 2nd operand or argument given to the operation.
 - SrcReg is the source register where the data is read from.
- Most, if not all instructions on the Tiva C are 8-bit instructions and can only take 8-bit values.

26.2 ARM's data formats

- Decimal numbers like 123.
- Hexadecimal numbers like 0x3F.
- n_xxx, where n is the base of the number from 2 to 9, and xxx is the number. For example, 8_12 is the octal number 12.
- A single character constant like 'A'.
- String constants like "string".

26.3 Syntax

26.3.1 Semicolon (;

; This is a comment.

Semicolons in ARM denote the start of a comment.

26.3.2 Hash (#)

#2

- The hash symbol (#) stands for a literal in ARM.
- Use the hash symbol to indicate numbers or strings.

26.3.2.1 Example

Copy the number 1 into the register R0.

`MOV R0, #1`

26.3.3 Square brackets ([])

[value{, optional_offset}]{!}
[value], {optional_offset} ; Post-indexed addressing

- Square brackets ([]) are the **value of** operator in ARM, which is equivalent to **dereferencing a pointer** in low-level programming languages like C or Rust.
- Use it to use the given value (value) as a memory address instead of a regular value.
- An optional offset (optional_offset) can be provided to add the offset to the given value to obtain the memory address.
- The ! represents write-back, and it is optional. Including the ! will update the value given to include the optional_offset, which means value becomes value + optional_offset after the instruction is done.
- The second form is for post-indexed addressing, which is when the value is used as the address for the memory access, then the optional_offset is applied to the address and written back to the register. Basically, value is used to access the memory, then once the memory is accessed, the optional_offset is added to value, so value becomes value + optional_offset.

26.3.3.1 Example 1

- Use the value in the R1 register as a memory address.
- Load into register R5 the data found at the memory address.

`LDR R5, [R1]`

26.3.3.2 Example 2

- Use the value in the R1 register as a memory address, and add 4 to the value.
- Load into register R6 the data found at the memory address.

`LDR R6, [R1, 4]`

26.3.3.3 Example 3

- Use the value in the R1 register as a memory address.
- Load into register R0 the data found at the memory address.
- Register R1 in this example is called the base address register.

`LDR R0, [R1] ; Equivalent to: LDR R0, [R1, #0]
; C code: R0 = memory[R1]`

26.3.3.4 Example 4

- Use the value in the R1 register as a memory address.
- Store into register R0 the data found at the memory address.
- Register R1 in this example is called the base address register.

```
STR R0, [R1]      ; Equivalent to: STR R0, [R1, #0]
; C code: memory[R1] = R0
```

26.3.3.5 Example 5

- Use the value in the R1 register as a memory address, offset by 4.
- Store into register R0 the data found at the memory address.
- Write the offset back into register R1, so that R1 becomes R1 + 4.

```
LDR R0, [R1, #4]!
```

26.3.3.6 Example 6

- Use the value in the R1 register as a memory address.
- Load into register R0 the data found at the memory address given by register R1.
- Offset the memory address in register R1 by 32 and save it back to register R1.

```
LDR R0, [R1], #32
```

26.4 Addressing modes

There are multiple addressing modes that can be used for loads and stores. The number in parentheses refers to the examples below:

- Register addressing, where the address is in a register (1).
- Pre-indexed addressing, where an offset to the base register is added before the memory access. The offset can be positive or negative and can be an immediate value of another register with an optional shift applied. (2), (3).
- Pre-indexed with write-back, which is indicated with an exclamation mark (!) added after the instruction. After the memory access has occurred, this updates the base register by adding the offset value (4).
- Post-index with write-back, where the offset is written after the square bracket. The address from the base register is only used for memory access, with the offset value added to the base register after the memory access (5).

; Address pointed to by R1
(1) LDR R0, [R1]

; Address pointed to by R1 + R2
(2) LDR R0, [R1, R2]

; Address is R1 + (R2 * 4)
(3) LDR R0, [R1, R2, LSL #2]

; Address pointed to by R1 + 32, then R1 = R1 + 32
(4) LDR R0, [R1, #32]!

; Read R0 from pointed to by R1, then R1 = R1 + 32
(5) LDR R0, [R1], #32

26.4.1 Examples with LDR

	Instruction	R0 =	R1 +=
Pre-index with write-back	LDR R0, [R1, #0x4]!	memory[R1 + 0x4]	0x4
	LDR R0, [R1, R2]!	memory[R1 + R2]	R2
	LDR R0, [R1, R2, LSR #0x4]!	memory[R1 + (R2 LSR 0x4)]	R2 LSR 0x4
Pre-index without write-back	LDR R0, [R1, #0x4]	memory[R1 + 0x4]	Not updated
	LDR R0, [R1, R2]	memory[R1 + R2]	Not updated
	LDR R0, [R1, -R2, LSR #0x4]	memory[R1 - (R2 LSR 0x4)]	Not updated
Post-index	LDR R0, [R1], #0x4	memory[R1]	0x4
	LDR R0, [R1, R2]	memory[R1]	R2
	LDR R0, [R1], R2 LSR #0x4	memory[R2]	R2 LSR 0x4

26.4.2 Syntax examples

The shift in the table below can be one of LSL, LSR, ASR or ROR, which are the bit shifting operations in ARM assembly.

Addressing mode and index method	Addressing syntax
Pre-index with immediate offset	[register #+/-offset]
Pre-index with register offset	[register_1 +/-register_2]
Pre-index with scaled register offset	[register_1 +/-register_2, shift #shift_amount]
Pre-index write-back with immediate offset	[register #+/-offset]!
Pre-index write-back with register offset	[register_1 +/-register_2]!
Pre-index write-back with scaled register offset	[register_1 +/-register_2, shift #shift_amount]!
Immediate post-indexed	[register], #+/-offset
Register post-indexed	[register_1], +/-register_2
Scaled register post-indexed	[register_1], +/-register_2, shift #shift_amount

26.5 Condition code suffixes

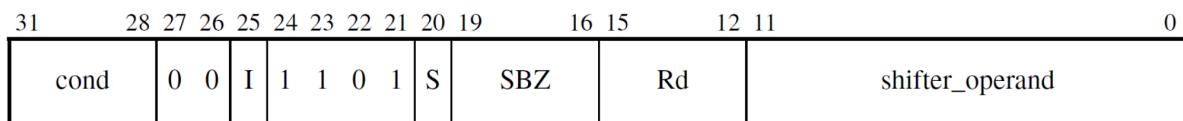

Opcode [31:28]	Suffix	Flags	Meaning
0000	EQ	Z = 1	Equal
0001	NE	Z = 0	Not equal
0010	CS or HS	C = 1	Higher or same, unsigned
0011	CC or LO	C = 0	Lower, unsigned
0100	MI	N = 1	Negative
0101	PL	N = 0	Positive or zero
0110	VS	V = 1	Overflow
0111	VC	V = 0	No overflow
1000	HI	C = 1 and Z = 0	Higher, unsigned
1001	LS	C = 0 or Z = 1	Lower or same, unsigned
1010	GE	N = V	Greater than or equal, signed
1011	LT	N \neq V	Less than, signed
1100	GT	Z = 0 and N = V	Greater than, signed
1101	LE	Z = 1 and N \neq V	Less than or equal, signed
1110	AL	Can have any value	Always, or unconditional. This is the default when no suffix is given.

26.6 ARM CPU instructions

ARM instructions are performed by the microprocessor when the program is being run, and are used to do useful things with the microprocessor, like read and modify data to perform a task.

26.7 MOV (Move)

`MOV{S}{condition} destination, data`

- The MOV instruction copies the data given into the destination register.
- Note that the MOV instruction only supports 8-bit values on the Tiva C.
- Larger values like 32-bit values need to be loaded in some other way, like the LDR pseudo-instruction ([page 482](#)).
- {S} is an optional suffix. If S is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when S is specified.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.7.1 Example

Copy the value 0x11 into the register R0.

`MOV R0, #0x11`

26.8 MVN (Move Not)

`MVN{S}{condition} destination, data`

- The MVN instruction performs a bitwise NOT on the data given and saves it into the destination register.
- It is the bitwise NOT operator on ARM.
- {S} is an optional suffix. If S is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when S is specified.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.8.1 Example

Invert the value of 4, which is 100 in binary, to obtain 011 in binary. Then copy the value of 011 into the register R2.

`MVN R2, #4`

26.9 MOVT (Move Top)

`MOVT{S}{condition} destination, data`

- The MOVT instruction is just like the MOV instruction ([page 480](#)), but copies the data given, a 16-bit half-word, into the **top** 16-bits of the register.
- {S} is an optional suffix. If S is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when S is specified.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.9.1 Example

Copy 0xFEED into the **top** 16-bits of register R3.

`MOVT R3, #0xFEED`

26.10 MOVW (Move Wide)

`MOVW{S}{condition} destination, data`

- The MOVW instruction is just like the MOV instruction ([page 480](#)), but copies the data given, a 16-bit half-word, into the **bottom** 16-bits of the register.
- {S} is an optional suffix. If S is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when S is specified.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.10.1 Example

Copy 0xC0DE into the **bottom** 16-bits of register R3.

`MOVW R3, #0xC0DE`

26.11 LDR (Load)

`LDR{condition} destination, source`

- The LDR instruction loads the value found at the given memory address (`source`), into the destination register.
- `{condition}` is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.11.1 Example

- Use the value in the R1 register as a memory address.
- Load into register R5 the data found at the memory address.

`LDR R5, [R1]`

26.11.2 Pseudo-instruction

`LDR destination, =value`

The LDR pseudo-instruction either loads a 32-bit immediate value or a memory address (`value`) into the destination register. This instruction is used mostly used to load 32-bit values that cannot be loaded with MOV instruction ([page 480](#)) into a register with one single instruction.

26.12 LDRD (Load Double-Word)

`LDRD{condition} destination, source`

- The LDRD instruction loads a **double-word** of the given source register into the destination memory address.
- The difference between LDRD and the LDR instruction ([page 482](#)) is that LDRD only loads a **double-word**, which is **8 bytes** instead of a **word**, which is **4 bytes**.
- `{condition}` is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.12.1 Example

- Use the value in register R1 as a memory address.
- loads a **double-word** from the memory address of R1, and save the contents in register R4.

`LDRD R4, [R1]`

26.13 LDRB (Load Byte)

`LDRB{condition} destination, source`

- The LDRB instruction loads a **byte** of the given source register into the destination memory address.
- The difference between LDRB and the LDR instruction ([page 482](#)) is that LDRB only loads a **byte**, which is **1 byte** instead of a **word**, which is **4 bytes**.
- `{condition}` is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.13.1 Example

- Use the value in register R1 as a memory address.
- loads a **byte** from the memory address of R1, and save the contents in register R4.

`LDRB R4, [R1]`

26.14 LDRSB (Load Signed Byte)

LDRSB{condition} destination, source

- The LDRSB instruction loads a **signed byte** of the given source register into the destination memory address.
- The difference between LDRSB and the LDR instruction ([page 482](#)) is that LDRSB only loads a **signed byte**, which is **1 signed byte** instead of a **word**, which is **4 bytes**.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.14.1 Example

- Use the value in register R1 as a memory address.
- loads a **signed byte** from the memory address of R1, and save the contents in register R4.

LDRSB R4, [R1]

26.15 LDRH (Load Half-Word)

LDRH{condition} destination, source

- The LDRH instruction loads a **half-word** of the given source register into the destination memory address.
- The difference between LDRH and the LDR instruction ([page 482](#)) is that LDRH only loads a **half-word**, which is instead of a **word**, which is **4 bytes**.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.15.1 Example

- Use the value in register R1 as a memory address.
- loads a **half-word** from the memory address of R1, and save the contents in register R4.

LDRH R4, [R1]

26.16 LDRSH (Load Signed Half-Word)

LDRSH{condition} destination, source

- The LDRSH instruction loads a **signed half-word** of the given source register into the destination memory address.
- The difference between LDRSH and the LDR instruction ([page 482](#)) is that LDRSH only loads a **signed half-word**, which is **2 signed bytes** instead of a **word**, which is **4 bytes**.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.16.1 Example

- Use the value in register R1 as a memory address.
- loads a **signed half-word** from the memory address of R1, and save the contents in register R4.

LDRSH R4, [R1]

26.17 STR (Store)

`STR{condition} destination, source`

- The STR instruction stores the value of the given source register into the destination memory address.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.17.1 Example 1

- Use the value in the R1 register as a memory address.
- Store the contents of register R3 into the memory address.

`STR R3, [R1]`

26.18 STRD (Store Double-Word)

`STRD{condition} destination, source`

- The STRD instruction stores a **double-word** of the given source register into the destination memory address.
- The difference between STRD and the STR instruction ([page 484](#)) is that STRD only stores a **double-word**, which is **8 bytes** instead of a **word**, which is **4 bytes**.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.18.1 Example

- Use the value in register R1 as a memory address.
- stores a **double-word** from the contents of register R4 into the memory address.

`STRD R4, [R1]`

26.19 STRB (Store Byte)

`STRB{condition} destination, source`

- The STRB instruction stores a **byte** of the given source register into the destination memory address.
- The difference between STRB and the STR instruction ([page 484](#)) is that STRB only stores a **byte**, which is **1 byte** instead of a **word**, which is **4 bytes**.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.19.1 Example

- Use the value in register R1 as a memory address.
- stores a **byte** from the contents of register R4 into the memory address.

`STRB R4, [R1]`

26.20 STRSB (Store Signed Byte)

`STRSB{condition} destination, source`

- The STRSB instruction stores a **signed byte** of the given source register into the destination memory address.
- The difference between STRSB and the STR instruction ([page 484](#)) is that STRSB only stores a **signed byte**, which is **1 signed byte** instead of a **word**, which is **4 bytes**.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.20.1 Example

- Use the value in register R1 as a memory address.
- stores a **signed byte** from the contents of register R4 into the memory address.

`STRSB R4, [R1]`

26.21 STRH (Store Half-Word)

`STRH{condition} destination, source`

- The STRH instruction stores a **half-word** of the given source register into the destination memory address.
- The difference between STRH and the STR instruction ([page 484](#)) is that STRH only stores a **half-word**, which is instead of a **word**, which is **4 bytes**.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.21.1 Example

- Use the value in register R1 as a memory address.
- stores a **half-word** from the contents of register R4 into the memory address.

`STRH R4, [R1]`

26.22 STRSH (Store Signed Half-Word)

`STRSH{condition} destination, source`

- The STRSH instruction stores a **signed half-word** of the given source register into the destination memory address.
- The difference between STRSH and the STR instruction ([page 484](#)) is that STRSH only stores a **signed half-word**, which is **2 signed bytes** instead of a **word**, which is **4 bytes**.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.22.1 Example

- Use the value in register R1 as a memory address.
- stores a **signed half-word** from the contents of register R4 into the memory address.

`STRSH R4, [R1]`

26.23 ADD (Add)

`ADD{S}{condition} {destination, }register, value`

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	0
cond	0	0	I	0	1	0	0	S	Rn	Rd					shifter operand

- The ADD instruction adds the value in the register with the value given and stores the result in the destination register.
- If the destination register is not given, the result will be stored in the given register.
- {S} is an optional suffix. If S is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when S is specified.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.23.1 Example 1

Add the value of R0 twice and store the result in register R1

`ADD R1, R0, R0`

26.23.2 Example 2

Add the value of R0 and 2 and store the result in register R2.

`ADD R2, R0, #2`

26.23.3 Example 3

Add the value of R0 and R0 shifted left by 2, and store the result in register R2.

`ADD R2, R0, R0, LSL #2`

26.23.4 Example 4

Add 4 to the value of the program counter (PC), which is the address of the ADD instruction itself plus 8 bytes and store the result in register R2.

`ADD R2, PC, #4`

26.24 ADC (Add with Carry)

`ADC{S}{condition} {destination, }register, value`

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	0
cond	0	0	I	0	1	0	1	S	Rn	Rd					shifter_operand

- The ADC instruction adds the value in the given register with the given value and stores the result in the destination register, which is the same as the ADD instruction ([page 486](#)), but it also adds the carry flag to the result of the addition.
- If the destination register is not given, the result will be stored in the given register.
- This instruction is usually used to add the overflow from a previous ADD instruction ([page 486](#)).
- {S} is an optional suffix. If S is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when S is specified.
- {condition} is an optional condition code suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.24.1 Example

- Use ADC to synthesise multi-word addition.
- If register pairs R0, R1 and R2, R3 hold 64-bit values, where R0 and R2 hold the least significant words, the following instructions leave the 64-bit sum in R4 and R5.

ADDS R4, R0, R2	R1 R0
ADC R5, R1, R3	+ R3 R2
	—————
	R5 R4

If the second instruction is changed from:

`ADC R5, R1, R3`

To:

`ADCS R5, R1, R3`

The resulting values of the flags indicate:

- N - The 64-bit addition produced a negative result.
- C - An unsigned integer overflow occurred.
- V - A signed integer overflow occurred.
- Z - The most significant 32 bits are all zero.

26.25 SADD16 and SADD8 (Signed Add)

SADD16{condition} {destination, }register_1, register_2
SADD8{condition} {destination, }register_1, register_2

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	8	7	6	5	4	3	0
cond	0	1	1	0	0	0	0	1			Rn		Rd		SBO	0	0	0	1		Rm

- The SADD16 and SADD8 instructions are signed add operations.
- Both add the values in `register_1` and `register_2` together and store the result in the `destination` register.
- If the `destination` register is not given, the result will be stored in `register_1`.
- They also set the GE bits in the current program status register (CPSR) according to the results of the additions.
- SADD16 performs two 16-bit signed integer additions while SADD8 performs 4 8-bit signed integer additions.

26.25.1 Example

Use the SADD16 instruction to speed up operations on arrays of half-word data. For example:

```
LDR    R3, [R0], #4      ; Load 4 bytes from R0 and skip to the next 4 bytes
LDR    R5, [R1], #4      ; Load 4 bytes from R1 and skip to the next 4 bytes
SADD16 R3, R3, R5       ; Add R3 and R5 together and store the result in R3
STR    R3, [R2], #4      ; Store 4 bytes in R3 and skip to the next 4 bytes
```

The above performs the same operations as the following:

```
LDRH   R3, [R0], #2      ; Load 2 bytes from R0 and skip to the next 2 bytes
LDRH   R4, [R1], #2      ; Load 2 bytes from R1 and skip to the next 2 bytes
ADD    R3, R3, R4       ; Add R3 and R4 together and store the result in R3
STRH   R3, [R2], #2      ; Store 2 bytes in R2 and skip to the next 2 bytes
```

26.26 SUB (Subtract)

`SUB{S}{condition} {destination, }register, value`

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	0
cond	0	0	I	0	0	1	0	S	Rn	Rd					shifter_operand

- The SUB instruction subtracts the given value from the value in the given register and stores the result in the destination register.
- If the destination register is not given, the result will be stored in the given register.
- {S} is an optional suffix. If S is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when S is specified.
- Borrow = NOT(Carry) = C - 1
- If the S suffix is set, the C flag is set to:
 - ▶ 1 if no borrow occurs.
 - ▶ 0 if a borrow does occur.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.26.1 Example

Use SUB to subtract one value from another. To decrement the value of register R0, use:

`SUB R0, R0, #1`

SUBS is useful as a loop counter decrement, as the loop branch can test the flags for the appropriate termination condition, without the need for a separate compare instruction:

`SUBS R0, R0, #1`

The code above both decrements the loop counter in R0 and checks whether it has reached zero.

26.27 SBC (Subtract with Carry)

`SUB{S}{condition} {destination, }register, value`

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	0
cond	0	0	I	0	1	1	0	S	Rn	Rd					shifter_operand

- The SBC instruction subtracts the carry (C) flag from the given value, as well as the value in the given register, and stores the result in the destination register.
- If the destination register is not given, the result will be stored in the given register.
- {S} is an optional suffix. If S is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when S is specified.
- Borrow = NOT(Carry) = C - 1
- If the S suffix is set, the C flag is set to:
 - 1 if no borrow occurs.
 - 0 if a borrow does occur.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.27.1 Example

Use SBC to synthesise multi-word subtraction. For example, if register pairs R0 and R1 and R2 and R3 hold 64-bit values (R0 and R2 hold the least significant words), the following instructions will leave the 64-bit difference in R4 and R5.

`SUBS R4, R0, R2
SUBS R5, R1, R3`

$$\begin{array}{r}
 & & & & R1 & + & C & - & 1 & R0 \\
 & & & & - & & R3 & & R2 \\
 \hline
 & & & & & & & & R5 & R4
 \end{array}$$

26.28 RSB (Reverse Subtract)

`RSB{S}{condition} {destination, }register, value`

- The RSB instruction subtracts the value in the register from the given value and stores the result in the destination register.
- If the destination register is not given, the result will be stored in the given register.
- {S} is an optional suffix. If S is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when S is specified.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.28.1 Example

Subtract the value in register R0 from 5, i.e. 5 - R0.

`RSB R0, R0, #5`

26.29 RSC (Reverse Subtract with Carry)

RSC{S}{condition} {destination, }register, value

- The RSC instruction subtracts the value in the register from the given value and stores the result in the destination register, which is the same as the RSB instruction ([page 490](#)), but it adds the negation of the carry flag to the result of the subtraction.
- If the destination register is not given, the result will be stored in the given register.
- This instruction is usually used to add the underflow, or borrow, from a previous RSB instruction ([page 490](#)).
- {S} is an optional suffix. If S is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when S is specified.
- {condition} is an optional condition code suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.29.1 Example

Add the negation of the carry flag to the value in register R2, then subtract the value in register R1 from R2, and store the result in register R0. Essentially, it is $R2 + C - 1$, where C is the carry flag.

RSC R0, R1, R2

26.30 SSUB16 and SSUB8 (Signed Subtract)

SSUB16{condition} {destination, }register_1, register_2

SSUB8{condition} {destination, }register_1, register_2

	31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	8	7	6	5	4	3	0
cond	0	1	1	0	0	0	0	1				Rn	Rd	SBO		0	1	1	1		Rm	

- The SSUB16 and SSUB8 instructions are signed subtract operations.
- Both subtract the value in register_2 from the value in register_1 and store the result in the destination register.
- If the destination register is not given, the result will be stored in register_1.
- They also set the GE bits in the current program status register (CPSR) according to the results of the additions.
- SADD16 performs two 16-bit signed integer additions while SADD8 performs 4 8-bit signed integer additions.

26.30.1 Example

- Use SSUB16 to for operations on arrays of half-word data. This is similar to the way you can use SADD16.
- You can also use SSUB16 for operations on complex numbers that are held as pairs of 16-bit integers of Q15 numbers. If you hold the real and imaginary parts of a complex number in the bottom and top half of a register respectively, then the instruction below will perform the complex arithmetic operation $R0 = R1 - R2$.

SSUB16 R0, R1, R2

26.31 MUL (Multiply)

`MUL{S}{condition} {destination, }register_1, register_2`

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	8	7	6	5	4	3	0
cond	0	0	0	0	0	0	0	S		Rd		SBZ		Rs	1	0	0	1		Rm	

- The **MUL** instruction multiplies two values from the registers and stores the least significant 32 bits of the result in the **destination** register.
- {S} is an optional suffix. If S is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when S is specified.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.31.1 Example

Multiply the value of R0 with R1 and store the result in register R2.

`MUL R2, R0, R1`

26.32 MLA (Multiply Accumulate)

`MLA{S}{condition} destination, register_1, register_2, add_register`

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	8	7	6	5	4	3	0
cond	0	0	0	0	0	0	1	S		Rd		Rn		Rs	1	0	0	1		Rm	

- The **MLA** instruction multiplies two values from the registers, then adds the value from the **add_register**, then stores the least significant 32 bits of the result in the **destination** register.
- Essentially, it does **destination = register_1 * register_2 + add_register**
- {S} is an optional suffix. If S is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when S is specified.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.32.1 Example

Multiply the value of R0 with R1, then add the value of R3, and store the result in register R2, i.e. $R2 = R0 * R1 + R3$.

`MLA R2, R0, R1, R3`

26.33 MLS (Multiply Subtract)

`MLA{S}{condition} destination, register_1, register_2, subtract_register`

- The MLS instruction multiplies two values from the registers, then subtracts the value in `subtract_register` from the result of the multiplication, then stores the least significant 32 bits of the result in the `destination` register.
- Essentially, it does `destination = register_1 * register_2 - subtract_register`
- `{S}` is an optional suffix. If `S` is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when `S` is specified.
- `{condition}` is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.33.1 Example

Multiply the value of R0 with R1, then subtract the value of R3 from the result, and store the result in register R2, i.e. $R2 = R0 * R1 - R3$.

`MLS R2, R0, R1, R3`

26.34 UMULL (Unsigned Multiply Long)

`UMULL{S}{condition} destination_low, destination_high, register_1, register_2`

	31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	8	7	6	5	4	3	0
cond	0	0	0	0	1	0	0	S		RdHi		RdLo		Rs		1	0	0	1		Rm	

- The UMULL instruction takes the values from registers `register_1` and `register_2` as unsigned integers and multiplies these two integers. Then it places the least significant 32 bits of the result in `destination_low` and the most significant 32 bits of the result in `destination_high`.
- `{S}` is an optional suffix. If `S` is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when `S` is specified.
- `{condition}` is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.34.1 Example

Multiply the values in R2 and R3 together, then places the least significant 32 bits of the result in R0, and the most significant 32 bits of the result in R1.

`UMULL R0, R1, R2, R3`

26.35 UMLAL (Unsigned Multiply Long with Accumulate)

`UMLAL{S}{condition} destination_low, destination_high, register_1, register_2`

- The UMLAL instruction takes the values from registers `register_1` and `register_2` as unsigned integers and multiplies these two integers. Then it adds the result to the 64-bit unsigned integer contained in `destination_low` and `destination_high`.
- {S} is an optional suffix. If S is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when S is specified.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.35.1 Example

Multiply the values in R2 and R3 together, then add the result to the 64-bit unsigned integer contained in R0 and R1.

`UMLAL R0, R1, R2, R3`

26.36 SMULL (Signed Multiply Long)

`SMULL{S}{condition} destination_low, destination_high, register_1, register_2`

- The SMULL instruction takes the values from registers `register_1` and `register_2` as two's complement signed integers and multiplies these two integers. Then it places the least significant 32 bits of the result in `destination_low` and the most significant 32 bits of the result in `destination_high`.
- {S} is an optional suffix. If S is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when S is specified.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.36.1 Example

Multiply the values in R2 and R3 together, then places the least significant 32 bits of the result in R0, and the most significant 32 bits of the result in R1.

`SMULL R0, R1, R2, R3`

26.37 SMLAL (Signed Multiply Long with Accumulate)

`SMLAL{S}{condition} destination_low, destination_high, register_1, register_2`

- The SMLAL instruction takes the values from registers `register_1` and `register_2` as two's complement signed integers and multiplies these two integers. Then adds the result to the 64-bit signed integer contained in `destination_low` and `destination_high`.
- {S} is an optional suffix. If S is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when S is specified.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.37.1 Example

Multiply the values in R2 and R3 together, then adds the result to the 64-bit signed integer contained in R0 and R1.

`SMLAL R0, R1, R2, R3`

26.38 UDIV (Unsigned Divide)

`UDIV{condition} {destination, }register_1, register_2`

- The UDIV instruction divides the 32-bit unsigned integer value in `register_1` by the 32-bit unsigned integer value in `register_2`, and stores the result in the `destination` register.
- If the `destination` register is not given, the result will be stored in `register_1`.
- `{condition}` is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.38.1 Example

Perform unsigned integer division by dividing the value in R2 by the value in R0, and store the result in the register R3.

`UDIV R3, R2, R0`

26.39 AND (Bitwise AND)

`AND{S}{condition} destination, register, value`

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	0
cond	0	0	I	0	0	0	0	S	Rn	Rd					shifter_operand

0	0	1	1	1	1	0	0	
AND	1	0	1	0	1	0	1	0
<hr/>								
0	0	1	0	1	0	0	0	

- The AND instruction performs a bitwise AND on the value from the `register` and the given `value`, and stores the result in the `destination` register.
- `{S}` is an optional suffix. If S is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when S is specified.
- `{condition}` is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.39.1 Example

Perform a bitwise AND on the value in R3 and R0 and store the result in register R4.

`AND R4, R3, R0`

26.39.2 Example of forcing bits to 0

- `R0 = 0000 0001 0001 0000`
- `~R0 = 1111 1110 1110 1111`
- `R1 = 0000 0000 0001 0001`
- `R3 = 1010 1011 1100 1101`

```
MOVW  R0, #0x0110      ; Bit mask
MVN   R0, R0          ; Invert the bit mask
AND   R2, R1, R0      ; Zero out the bits in R1 that are also in the mask
AND   R4, R3, R0      ; Zero out the bits in R3 that are also in the mask
```

Result:

- `R2 = 0000 0000 0000 0001`
- `R4 = 1010 1010 1100 1101`

26.40 ORR (Bitwise OR)

ORR{S}{condition} destination, register, value

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	0
cond	0	0	I	1	1	0	0	S	Rn	Rd					shifter_operand

0	0	1	1	1	1	0	0	
OR	1	0	1	0	1	0	1	0
	1	0	1	1	1	1	0	

- The ORR instruction performs a bitwise OR on the value from the register and the given value, and stores the result in the destination register.
- {S} is an optional suffix. If S is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when S is specified.
- {condition} is an optional condition code suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.40.1 Example

Perform a bitwise OR on the value in R1 and R0 and store the result in register R2.

ORR R2, R1, R0

26.40.2 Example of forcing bits to 1

- R0 = 0000 0001 0001 0000
- R1 = 0000 0000 0001 0001
- R3 = 1010 1011 1100 1101

```
MOVW R0, #0x0110 ; Bit mask
ORR R2, R1, R0 ; Force the bits in R1 that are also in the mask to be 1
ORR R4, R3, R0 ; Force the bits in R3 that are also in the mask to be 1
```

Result:

- R2 = 0000 0001 0001 0001
- R4 = 1010 1011 1101 1101

26.41 EOR (Exclusive OR, XOR)

EOR{S}{condition} destination, register, value

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	0
cond	0	0	I	0	0	0	1	S	Rn		Rd		shifter_operand		

$$\begin{array}{r} 0 \ 0 \ 1 \ 1 \ 1 \ 0 \ 0 \\ \text{XOR} \ 1 \ 0 \ 1 \ 0 \ 1 \ 0 \ 0 \\ \hline 1 \ 0 \ 0 \ 1 \ 0 \ 1 \ 1 \ 0 \end{array}$$

- The EOR instruction performs a bitwise XOR, or exclusive OR on the value from the register and the given value, and stores the result in the destination register.
- {S} is an optional suffix. If S is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when S is specified.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.41.1 Example

Perform a bitwise XOR, or exclusive OR, on the value in R1 and R0 and store the result in register R2.

EOR R2, R1, R0

26.41.2 Example of flipping bits

- R0 = 0000 0001 0001 0000
- R1 = 0000 0000 0001 0001
- R3 = 1010 1011 1100 1101

```
MOVW R0, #0x0110 ; Bit mask
EOR R2, R1, R0 ; Flip the bits in R1 that are also in the mask
EOR R4, R3, R0 ; Flip the bits in R3 that are also in the mask
```

Result:

- R2 = 0000 0001 0000 0001
- R4 = 1010 1010 1101 1101

26.42 BIC (Bit Clear)

BIC{S}{condition} destination, source, bits

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	0
cond	0	0	I	1	1	1	0	S	Rn	Rd					shifter_operand

$$\begin{array}{r} 0 \ 0 \ 1 \ 1 \ 1 \ 1 \ 0 \ 0 \\ BIC \ 1 \ 0 \ 1 \ 0 \ 1 \ 0 \ 1 \ 0 \\ \hline 0 \ 0 \ 0 \ 1 \ 0 \ 1 \ 0 \ 0 \end{array}$$

- The BIC (bit clear) instruction performs a bitwise AND ([page 495](#)) on the bits in the source register with the complements of the corresponding bits in the bits given, then copies the result to the destination register.
- Essentially, it does source AND NOT bits and copies the result to the destination register.
- If the documentation above still does not make sense, the instruction's name should give a good idea of what it does.
- Basically, to clear a bit (i.e. set the bit to 0) in the source register, the bits to clear should be indicated by a 1 in the binary value given in bits.
- To clear a byte instead, provide a hexadecimal value with the byte to clear indicated as F to clear a whole byte at once.
- {S} is an optional suffix. If S is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when S is specified.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

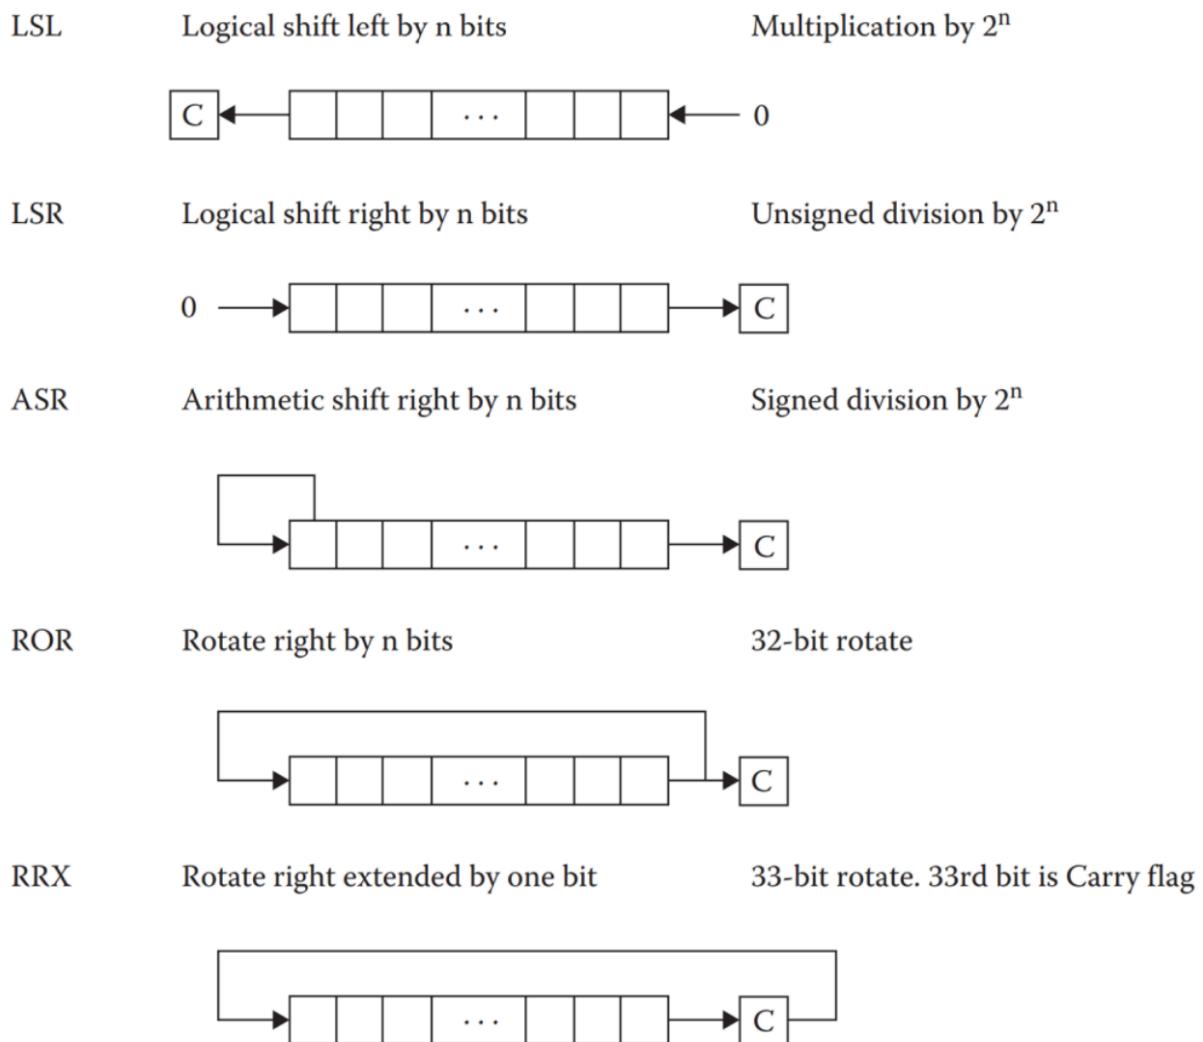

26.42.1 Example

Clear the last byte in the register R1 and copy the result to register R2.

BIC R2, R1, #0xF

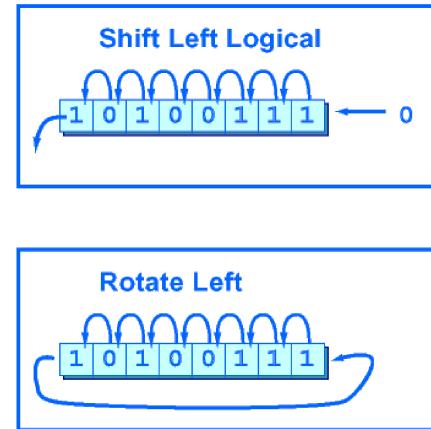

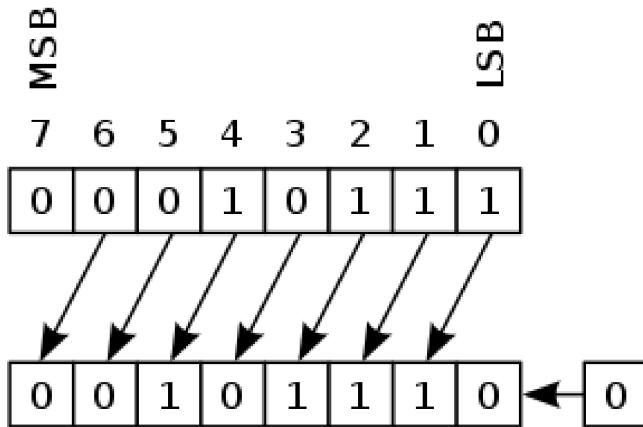

26.43 Shift operators

- LSL: Logical shift left
 - $x \ll y$ the least significant bits are filled with zeros.
- LSR: Logical shift right
 - $(\text{unsigned}) x \gg y$ the most significant bits are filled with zeros.
- ASR: Logical shift right
 - $(\text{signed}) x \gg y$, copy the sign bit to the most significant bit.
- ROR: Rotate right
 - $((\text{unsigned}) x \gg y) | (x \ll (32 - y))$.
- RRX: Rotate right extended
 - $C \ll 31 | ((\text{unsigned}) x \gg 1)$
 - Performs 33-bit rotate, with the current program status register's C bit being inserted above the sign bit of the word.

26.44 LSL (Logical Shift Left)

`LSL{S}{condition} destination, value, shift_amount`

- The LSL instruction performs a bitwise logical shift left on the given value by the given `shift_amount`.
- The least significant bits are filled with zeros.
- This is equivalent to C's value `<< shift_amount`.
- {S} is an optional suffix. If S is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when S is specified.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.44.1 Example 1

Perform a logical left shift by 2 bits on the value in register R1 and store the result in register R0.

`LSL R0, R1, #2`

26.44.2 Example 2

```

AREA    Prog1, CODE, READONLY
ENTRY
    MOV    R0, #0x11    ; Load initial value
    LSL    R1, R0, #1    ; Shift 1 bit left
    LSL    R2, R1, #1    ; Shift 1 bit left

stop   B    stop      ; Stop program
END

```

26.44.3 Example 3

Example of doing n! (factorial of n).

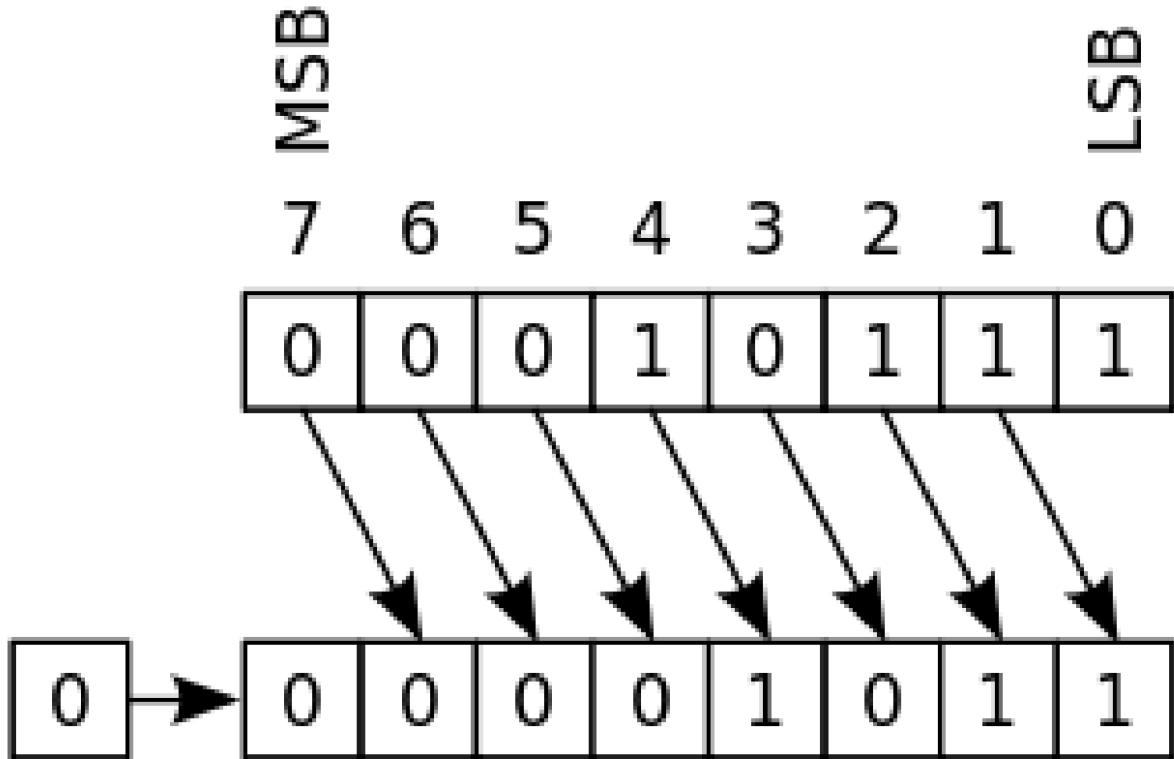

```

AREA    Prog2, CODE, READONLY
ENTRY
    MOV    R6, #10      ; Load n into R6
    MOV    R7, #1        ; Initial value of n! is 1, for the case of n = 0
loop   CMP    R7, #0      ; Compare R6 with 0
    MULGT R7, R6, R7    ; n(n - 1)(n - 2) * ... * 2 * 1
    SUBGT R6, R6, #1    ; Decrement n by 1
    BGT   loop          ; Multiply again if the counter isn't 0
stop   B    stop      ; Stop program
END

```

26.45 LSR (Logical Shift Right)

`LSR{S}{condition} destination, value, shift_amount`

- The LSR instruction performs a bitwise logical shift right on the given `value` by the given `shift_amount`.
- {S} is an optional suffix. If S is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when S is specified.
- {condition} is an optional condition code suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

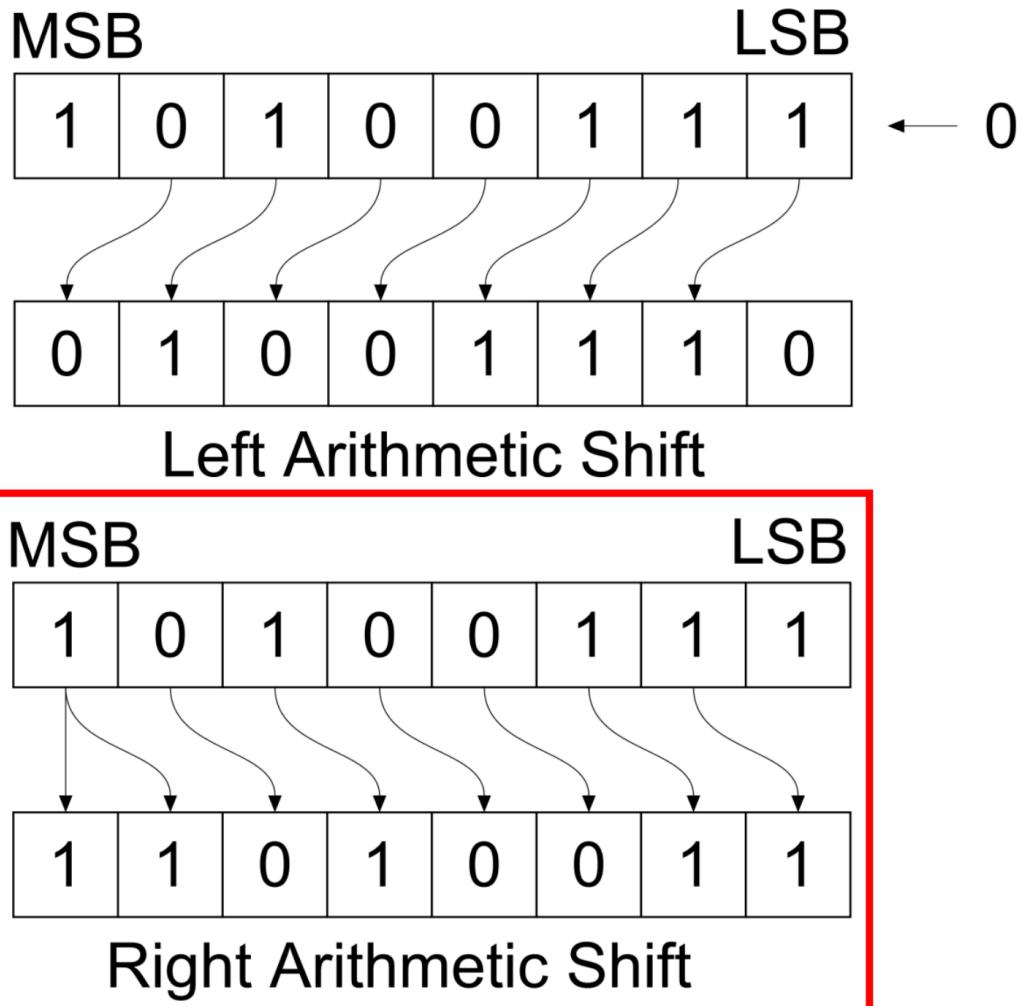

26.45.1 Example

Perform a logical right shift by 6 bits on the value in register R1 and store the result in register R0.

`LSR R0, R1, #6`

26.46 ASR (Arithmetic Shift Right)

`ASR{S}{condition} destination, value, shift_amount`

- The ASR instruction performs a bitwise arithmetic shift right on the given value by the given `shift_amount`.
- The only difference between ASR and LSR ([page 501](#)), or an arithmetic right shift and a logical right shift, is that the highest bit is preserved when doing an arithmetic right shift, while a logical right shift will just set the highest bit to 0. This is useful for calculating signed integers, as the arithmetic right shift will preserve the sign of the integer, i.e. a negative integer will remain negative, while you lose the sign when doing a logical right shift.
- {S} is an optional suffix. If S is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when S is specified.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

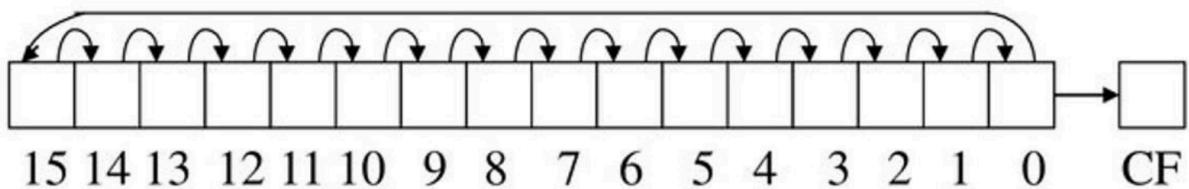

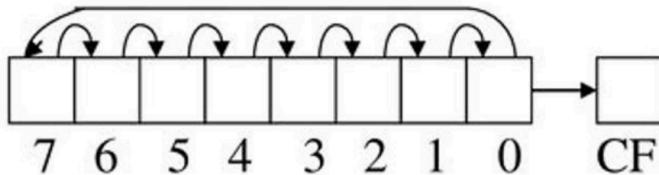

26.46.1 Example

Perform an arithmetic right shift by 4 bits on the value in register R1 and store the result in register R0.

`ASR R0, R1, #4`

26.47 ROR (Rotate Right)

ROR{S}{condition} destination, value, shift_amount

$x >> y; \quad y=7$

$$y = 7; 32 - y = 25; \quad 25 + 6 = 31$$

$(0000000b31\dots b7) | (b6\dots b0 \dots 0)$

- The ROR instruction rotates the given `value` right by the given `shift_amount`.
- Essentially, what this instruction does is the same as the LSR instruction ([page 501](#)), or logical shift right, but instead of replacing the highest bits with zeros, they are instead replaced with the lowest bits that are shifted off.
- {S} is an optional suffix. If S is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when S is specified.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

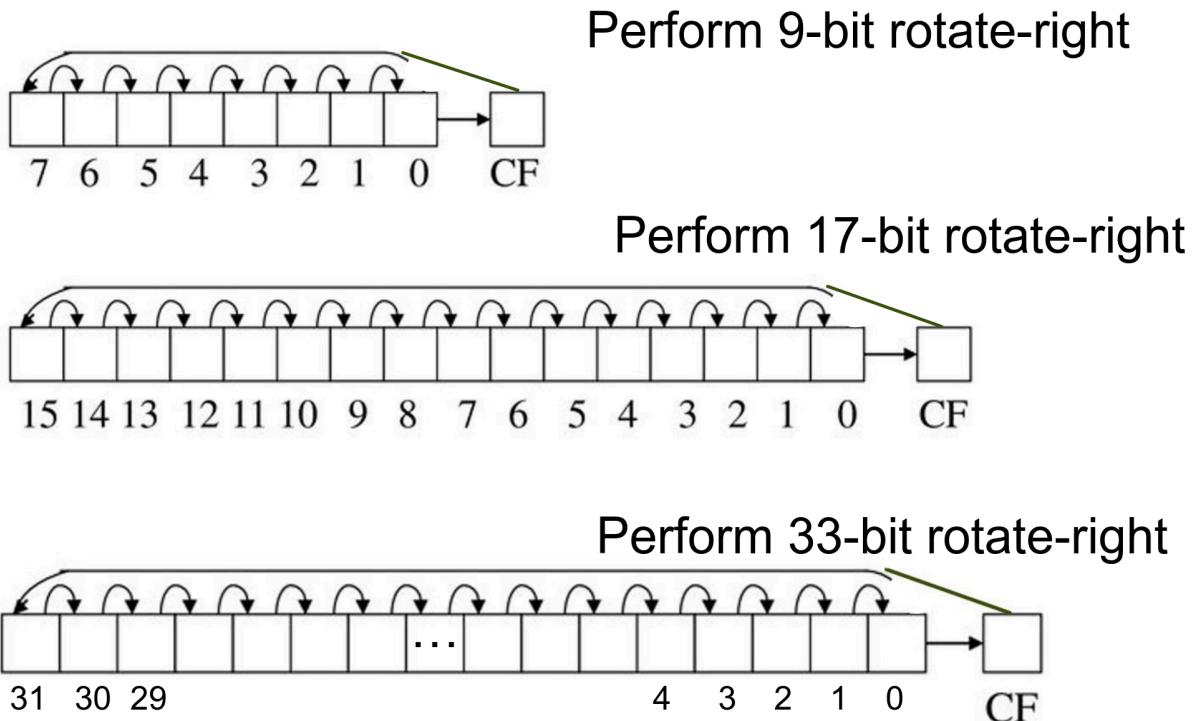

26.47.1 Example

Rotate the value in register R1 right by 2 bits and store the result in register R0.

ROR R0, R1, #2

26.48 RRX (Rotate Right Extended)

RRX{S}{condition} destination, value, shift_amount

- The ROR instruction rotates the given value right by the given shift_amount, but also writes to the carry (C) flag.
- Essentially, what this instruction does is the same as the LSR instruction ([page 503](#)), or rotate right, but instead of just having 32-bits to rotate around, there are 33-bits thanks to the carry (C) flag being included.
- {S} is an optional suffix. If S is specified, the condition flags are updated on the result of the operation. In other words, the current program status register (CPSR) is updated when S is specified.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.48.1 Example

Rotate the value in register R1 right by 10 bits, including the carry bit (C) and store the result in register R0.

RRX R0, R1, #10

26.49 B (Branch)

B{condition}{.W} label

31	28	27	26	25	24	23	0
cond	1	0	1	L			signed_immed_24

- The B instruction tells the microprocessor to branch to a different part of the code, which is indicated by the label.
- label can also be a register containing a memory address.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.49.1 Example 1

Go to the section of the code labelled loop.

B loop

26.49.2 Example 2

Go to the section of the code labelled loop if the carry flag is clear.

BCC loop

26.49.3 Example 3

Go to the section of the code labelled loop if the zero flag is set

BEQ loop

26.50 BL (Branch with Link)

BL{condition}{.W} label

- The BL instruction tells the microprocessor to branch to a different part of the code, which is indicated by the label, which is the same function as the B instruction ([page 505](#)), but also copies the memory address of the next instruction into the link register LR.
- This instruction is normally used with the BX instruction ([page 506](#)), where the BL instruction will jump to a section of code to perform a certain task, and the BX instruction will be used to jump back to the link register LR to continue executing from where it left off.
- label can also be a register containing a memory address.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.50.1 Example

Branch into the section of the code named function and save the memory address of the next instruction into the link register LR.

BL function

26.51 BX and BXNS (Branch and Exchange, and Branch and Exchange Non-Secure)

`BX{condition} register`
`BXNS{condition} register`

- The `BX` instruction tells the microprocessor to branch to the address contained in `register` and exchanges the instruction set if necessary.
- The `BXNS` instruction performs the same function as the `BX` instruction, but also transitions from the secure to the non-secure domain.
- If the first bit of the address contained in `register` is 0, the processor changes to, or remains in ARM state.
- If the first bit of the address contained in `register` is 1, the processor changes to, or remains in Thumb state.
- This instruction is normally used with the `BL` instruction ([page 505](#)), where the `BL` instruction will jump to a section of code to perform a certain task, and the `BX` instruction will be used to jump back to the link register `LR` to continue executing from where it left off.

26.51.1 Example 1

Branch to the link register, which is usually used to return from a function in ARM assembly.

`BX LR`

26.51.2 Example 2

```
; Subroutine call to function
BL func

func
    ; Function body

    ; Code
    ; Code
    ; Code

    ; R15 = R14, set the program counter to the value of the link register.
    ;
    ; This jumps out of the function
    ; and goes back to the instruction after the BL.
    MOV PC, LR

    ; Branch to the address in R12 and
    ; begin ARM execution if bit 0 of R12 is zero.
    ; Otherwise, continue executing thumb code.
    BX R12
```

26.52 ADR

`ADR destination, label`

- The `ADR` instruction loads a memory address to the `destination` register.
- The `label` is the label of the memory address to load. Note that it must be defined in the **same** code section.

26.52.1 Example

Get the memory address of `var_a` and save it in register `R0`.

`ADR R0, var_a`

26.53 CMP (Compare)

`CMP{condition} register, value`

- The `CMP` instruction compares whether the value in the `register` is the same as the given `value`, and updates the condition flags ([page 480](#)) on the result.
- This instruction does not place the result in any register.
- `CMP` subtracts the given `value` from the value in the `register`.
- `{condition}` is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.53.1 Example

Check whether the value in register `R1` is equal to 1.

`CMP R1, #1`

26.54 CMN (Compare Negative)

`CMN{condition} register, value`

- The `CMN` instruction compares whether the value in the `register` is the same as the given `value`, and updates the condition flags ([page 480](#)) on the result.
- This instruction does not place the result in any register.
- `CMN` adds the given `value` to the value in the `register`.
- `{condition}` is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.

26.54.1 Example

Check whether the value in register `R0` is **not** equal to 1.

`CMN R0, #1`

26.55 TEQ (Test Equivalence)

TST{condition} register, value

31	28	27	26	25	24	23	22	21	20	19	16	15	12	11	0
cond	0	0	I	1	0	0	1	1	Rn	SBZ			shifter_operand		

- The TEQ instruction tests the value in the register for equality with the value given, and updates the condition flags ([page 480](#)).
- More specifically, the TEQ instruction performs a **bitwise XOR or Exclusive OR** operation on the value in register and the given value.
- It is the same as the E0RS instruction ([page 497](#)), but the result is discarded.
- This instruction is the same as `register == value` in higher level programming languages like C and Python.
- This instruction does not store the result in any register, and only updates the condition flags.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.
- Use the TEQ instruction to test if two values are equal without affecting the V or C flags.
- TEQ is also useful for testing the sign of a value. After the comparison, the N flag is the logical Exclusive OR of the sign bits of the two given values.

26.55.1 Example

Conditionally test if the value in R10 is equal to the value in R9. The application program status register (APSR) is updated, but the result is discarded.

`TEQEQ R10, R9`

26.56 TST (Test bits)

TST{condition} register, value

- The TST instruction performs a **bitwise AND** operation on the value in register and the given value.
- It is the same as the ANDS instruction ([page 495](#)), but the result is discarded.
- This instruction does not store the result in any register, and only updates the condition flags.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.
- To test whether a bit of the given register is 0 or 1, use the TST instruction with a constant that has that bit set to 1 and all other bits cleared to 0.

26.56.1 Example

Perform bitwise AND of the value in R0 to 0x3F8. The application program status register (APSR) is updated, but the result is discarded.

`TST R2, #1`

26.57 Vector floating point (VFP) operations

- Before performing any vector floating point (VFP) operations on the Tiva C microcontroller, the floating point unit (FPU) needs to be enabled.
- The processor must be in privileged mode to read from and write to the Coprocessor Access Control (CPAC) register.
- The code below enables the FPU in both privileged and user modes.

```
; CPAC register is located ad address 0xE000ED88,  
; so load the address into a register  
; using the LDR pseudo-instruction as it is 32-bit  
LDR R0, =0xE000ED88  
  
; Read from the CPAC register into another register  
LDR R1, [R0]  
  
; Set bits 20 - 23 to enable CP10 and CP11 coprocessors  
ORR R1, R1, #(0xF << 20)  
  
; Write the modified value back to the CPAC register  
STR R1, [R0]
```

- All VFP operations basically perform the same function as their non VFP counterparts, but manipulate data on either a single-precision or a double-precision floating point register.
- A single-precision floating point register is usually a register on the floating point unit (FPU) starting with S, like S0 and S1. A single-precision floating point register can hold 32-bits.
- A double-precision floating point register is usually a register on the floating point unit (FPU) starting with D, like D0 and D1. A double-precision floating point register can hold 64-bits.

26.58 VLDR (Vector Load)

```
VLDR{condition}.32 destination, value  
VLDR{condition}.64 destination, value
```

- VLDR performs the same function as the LDR instruction ([page 482](#))
- The main difference with VLDR and LDR is that the destination can either be a single-precision, like S0 and S1, or double-precision floating point register, like D0 and D1.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.
- The .32 and .64 part of the instruction is optional.

26.58.1 Example

Load the value from the memory address in the register R6 offset by 8 into the single-precision floating point register S5.

```
VLDR S5, [R6, #08]
```

26.59 VSTR (Vector Load)

VSTR{condition}.32 destination, value
VSTR{condition}.64 destination, value

- VSTR performs the same function as the STR instruction ([page 484](#))
- The main difference with VSTR and STR is that the destination can either be a single-precision, like S0 and S1, or double-precision floating point register, like D0 and D1.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.
- The .32 and .64 part of the instruction is optional.

26.59.1 Example

Store the value from the single-precision floating point register S5 to the memory address in the register R6.

VSTR R6, S5

26.60 VMOV (Vector Move)

VMOV{condition}.F32 destination, value
VMOV{condition}.F64 destination, value

- VMOV performs the same function as the MOV instruction ([page 480](#))
- The main difference with VMOV and MOV is that the destination can either be a single-precision, like S0 and S1, or double-precision floating point register, like D0 and D1.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.
- The 32 and 64 part of the instruction is optional.

26.60.1 Example

Load the value from register R6 into single-precision register S12, and the value from register R11 into single-precision register S13.

VMOV S12, S13, R6, R11

26.61 VADD (Vector Add)

VADD{condition}.F32 destination, value
VADD{condition}.F64 destination, value

- VADD performs the same function as the ADD instruction ([page 486](#))
- The main difference with VADD and ADD is that the destination can either be a single-precision, like S0 and S1, or double-precision floating point register, like D0 and D1.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.
- The 32 and 64 part of the instruction is optional.

26.61.1 Example

Add the value from single-precision registers S1 and S0 and store the result in single-precision register S2.

VADD.F S2, S1, S0

26.62 Directives

- Directives are **not** CPU instructions, as they are not executed by the CPU when running the program.
- Instead, directives are instructions to the assembler, which is the ARM assembler (`armasm`) if you are using the ARM Keil IDE.
- If you are using GCC or ArmClang, then the directives would differ from the ones listed below.

26.63 Allocating memory to house instructions or data

{label} {instruction | directive | pseudo_instruction}

- The `label` is the label for the memory allocation.
- `{instruction | directive | pseudo_instruction}` is the CPU instructions or assembler directives to execute.

26.63.1 Example

```
EXPORT Start      ; Export the start label of the program

          ; Assembler directive to allocate memory for code
AREA ARMEx, CODE, READONLY

Start    MOV R0, #10      ; Label and processor instruction
          MOV R1, #3       ; Another processor instruction
stop     B  stop        ; Label and another processor instruction
          END            ; Assembler directive signifying the end of the file
```

26.64 SETS

{name} SETS string

The SETS directive sets a string value to a variable given by `{name}`.

- `string` is the string the variable is set to.

26.64.1 Example

Set the variable `my_text` to the string, "This is my text".

```
my_text SETS "This is my text"
```

26.65 EQU

{name} EQU number{, type}

The EQU directive sets a number value to a variable given by `{name}`.

- `number` is the number the variable is set to.
- `type` is optional, and it refers to the type of the number given to the EQU directive.

26.65.1 Example

Set the variable `temperature` to the number 25.6.

```
temperature EQU 25.6
```

26.66 RN

name RN expression

The RN directive defines a name for a specified register.

- name is the name to be assigned to the register. name cannot be the same as any of the predefined names.
- expr is either a register like R0, or a register number from 0 to 15.

26.66.1 Example

Define the name regname for the register r11.

```
regname RN 11
```

26.67 MACRO and MEND

MACRO

```
{$label}      macro_name{$condition} {$parameter_1{, $parameter_2}...}
; Code for the macro
MEND
```

- The MACRO directive signifies the start of the definition of a macro.
- Likewise, the MEND directive signifies the end of the definition of a macro.
- Take note that the \$ characters are required in a macro definition.
- The label is the label for the start of the macro.
- {condition} is an optional condition suffix. Refer to the condition code suffixes ([page 480](#)) for more information on the available suffixes and what they mean.
- parameter_1, parameter_2, ... are the parameters the macro can take.

26.67.1 Example 1

MACRO

```
; Macro definition
; var_a = 8 * (var_b + var_c + 6)
$Label_1      AddMul $var_a, $var_b, $var_c

$Label_1
; Add var_a, var_b and var_c together
; and store the result in var_a
ADD $var_a, $var_b, $var_c

; Add 6 to var_a
ADD $var_a, $var_a, #6

; Bitwise shift var_a left by 3 bits.
; This basically multiplies var_a by 8,
; since 2^3 is 8.
LSL $var_a, $var_a, #3
```

MEND

When the above macro is invoked using:

```
AddMul R0, R1, R2
```

It expands into:

```
ADD R0, R1, R2
ADD R0, R1, #6
LSL R0, R1, #3
```

26.67.2 Example 2

Macro definition:

```
MACRO ; Start of macro definition
$label xmac $p1, $p2
; Code
$label.loop1 ; Code
; Code
BGE $label.loop1
$label.loop2 ; Code
BL $p1
BGT $label.loop2
; Code
ADR $p2
MEND ; End of macro definition
```

When the macro is invoked, it expands into:

```
abc xmac subr1,de ; Macro invocation
; Below this line is what the macro is expanded into
; Code
abcloop1 ; Code
; Code
BGE abcloop1
abcloop2 ; Code
BL subr1
BGT abcloop2
; Code
ADR de
; Code
```

26.68 AREA

```
AREA section_name{, attribute_1, attribute_2, ...}
```

The AREA directive instructs the assembler to assemble a new code or data section.

- `section_name` is the name of the section, which can be anything.
- `attribute_1, attribute_2, ...` are the section attributes in ARM.

26.68.1 Valid section attributes

Attribute	Description
ALIGN= <i>expr</i>	This aligns a section on a 2 <i>expr</i> -byte boundary. Note that this is different from the ALIGN directive. For example, if <i>expr</i> = 10, then the section is aligned to a 1 KB boundary.
CODE	This section is machine code (READONLY is the default).
DATA	This section is data (READWRITE is the default).
READONLY	This section can be placed in read-only memory (default for sections of CODE).
READWRITE	This section can be placed in read-write memory (default for sections of DATA).

26.68.2 Example

Defines new code (CODE) section called `main` which is read-only (READONLY).

```
AREA main, CODE, READONLY
```

26.69 ENTRY and END

ENTRY

```
; Code  
END
```

- The ENTRY directive specifies the entry point of the program.
- In simpler terms, it tells the computer which part of the code to start executing from when running the program.
- All programs must have an entry point.
- If the program contains multiple entry points, you must select one of them by exporting the symbol for the ENTRY directive that you want to use as the entry point.

26.69.1 Example

```
AREA      ARMEx, CODE, READONLY  
  
; Entry point for the application  
ENTRY  
  
; Export the symbol so the linker can find it  
; in the object file.  
EXPORT Start  
Start  
; Code  
END
```

26.70 DCB (Declare 8-bit bytes)

{label} DCB{U} value_1{, value_2, value_3, ...}

- The DCB directive allocates one or more bytes (8-bit value for ARM), aligned on 1-byte (8-bit) boundaries.
- It also initialises the memory with the value given to it, value_1.
- {, value_2, value_3, ...} are additional values to be initialised.
- {label} is an optional label to place the initialised memory in.
- {U} is an optional suffix that tells the assembler to **not** align the memory on 1-byte (8-bit) boundaries.

26.70.1 Example 1

Define 3 bytes (8-bit values) in the data1 section, the first containing the decimal value 1, the next containing the decimal value 5, and the last one containing the decimal value 20.

```
data1 DCB 1, 5, 20
```

26.70.2 Example 2

Define 1 byte (8-bit value) in the data2 section, containing 4 + the address of the label mem06. Essentially, the bytes initialised will contain the memory address in the label mem06 offset by 4.

```
data2 DCB mem06 + 4
```

26.70.3 Example 3

Define 3 bytes (8-bit values) in the data1 section, the first containing the decimal value 1, the next containing the decimal value 5, and the last one containing the decimal value 20. However, the memory is not aligned to bytes boundaries (1-byte or 8-bit boundaries).

```
data3 DCB 1, 5, 20
```

26.71 DCW (Declare 16-bit half-words)

```
{label} DCW{U} value_1{, value_2, value_3, ...}
```

- The DCW directive allocates one or more half-words (16-bit value for ARM), aligned on 2-byte (16-bit) boundaries.
- It also initialises the memory with the value given to it, value_1.
- {, value_2, value_3, ...} are additional values to be initialised.
- {label} is an optional label to place the initialised memory in.
- {U} is an optional suffix that tells the assembler to **not** align the memory on 2-byte (16-bit) boundaries.

26.71.1 Example 1

Define 3 half-words (16-bit values) in the data1 section, the first containing the decimal value 1, the next containing the decimal value 5, and the last one containing the decimal value 20.

```
data1 DCW 1, 5, 20
```

26.71.2 Example 2

Define 1 half-word (16-bit value) in the data2 section, containing 4 + the address of the label mem06. Essentially, the half-words initialised will contain the memory address in the label mem06 offset by 4.

```
data2 DCW mem06 + 4
```

26.71.3 Example 3

Define 3 half-words (16-bit values) in the data1 section, the first containing the decimal value 1, the next containing the decimal value 5, and the last one containing the decimal value 20. However, the memory is not aligned to half-words boundaries (2-byte or 16-bit boundaries).

```
data3 DCW 1, 5, 20
```

26.72 DCD (Declare 32-bit words)

```
{label} DCD{U} value_1{, value_2, value_3, ...}
```

- The DCD directive allocates one or more words (32-bit value for ARM), aligned on 4-byte (32-bit) boundaries.
- It also initialises the memory with the value given to it, value_1.
- {, value_2, value_3, ...} are additional values to be initialised.
- {label} is an optional label to place the initialised memory in.
- {U} is an optional suffix that tells the assembler to **not** align the memory on 4-byte (32-bit) boundaries.

26.72.1 Example 1

Define 3 words (32-bit values) in the `data1` section, the first containing the decimal value 1, the next containing the decimal value 5, and the last one containing the decimal value 20.

```
data1 DCD 1, 5, 20
```

26.72.2 Example 2

Define 1 word (32-bit value) in the `data2` section, containing `4 + the address of the label mem06`. Essentially, the words initialised will contain the memory address in the label `mem06` offset by 4.

```
data2 DCD mem06 + 4
```

26.72.3 Example 3

Define 3 words (32-bit values) in the `data1` section, the first containing the decimal value 1, the next containing the decimal value 5, and the last one containing the decimal value 20. However, the memory is not aligned to words boundaries (4-byte or 32-bit boundaries).

```
data3 DCD 1, 5, 20
```

26.73 ALIGN

```
ALIGN {byte_boundary_size{, offset}}
```

The ALIGN directive aligns the current location within the code to a word (4-byte or 32-bit) boundary.

- byte_boundary_size is the size of the next byte boundary to align the current location on. It can be any power of 2 from 2 to 2^{31} , and the current location will be aligned to the next 2^n -byte boundary. If this parameter is not given, the instruction location will be set to the next word boundary.
- offset is optional, and is the byte offset from the alignment given in byte_boundary_size.
- Note that the current location in bytes is given by ($\text{offset} + n \times \text{byte_boundary_size}$), where n is the constant needed to get to the next byte_boundary_size boundary

26.73.1 Example 1

```
AREA cacheable, CODE, ALIGN=3
rout1 ; Code      ; Aligned on 8-byte boundary
       ; Code
       MOV pc, lr ; Aligned only on 4-byte boundary
       ALIGN 8    ; Now aligned on 8-byte boundary
rout2 ; Code
```

26.73.2 Example 2

```
AREA OffsetExample, CODE

; Place 1 byte at the start.
; Let's call this byte 1.
DCB 1

; Offset 3 bytes from the current location,
; then align on the next 4-byte boundary.
ALIGN 4, 3

; Current location is now 3 bytes away
; from the very first byte or byte 1.
;
; The first 3 bytes come from the offset given
; to the ALIGN directive, which is 3-bytes away
; from the boundary, so the current location is at byte 4.
;
; Byte 4 is the start of a 4-byte boundary,
; so it is already at the next word boundary to align on,
; and there is nothing else to do.
; There is no need to move to the next 4-byte boundary.
;
; Hence, the second byte from the second DCB directive
; is placed at byte 4, or 3 bytes away from the very first byte.
DCB 1
```

Below is an image to illustrate the alignment.

26.74 SPACE

`{label} SPACE bytes`

The SPACE directive reserves a zeroed block of memory, which is basically just setting the block of memory to 0.

- `{label}` is an optional label to place the memory in.
- `bytes` is the number of bytes of memory to zero.

26.74.1 Example

Fill 255 bytes of memory with 0.

`SPACE 255`

26.75 FILL

`{label} FILL bytes{, value{, value_size_in_bytes}}`

The FILL directive is similar to the SPACE directive ([page 518](#)), but it fills the memory with the given value instead of zero.

- `{label}` is an optional label to place the memory in.
- `bytes` is the number of bytes of memory to fill up with the `value`.
- `value` is the value used to fill the memory with, and it is optional as it will default to 0 if not given.
- `value_size_in_bytes` is the size of the `value` given in bytes, and is optional.

26.75.1 Example

Fill 50 bytes of memory with the hexadecimal value 0xAB, which is 1 byte in size.

`FILL 50, 0xAB, 1`

26.76 LTORG (Lookup table organised)

LTORG

- The LTORG directive instructs the assembler to assemble the current literal pool immediately.
- The assembler assembles the current literal pool at the end of every code section.
- The end of a code section is determined by the AREA ([page 513](#)) directive at the beginning of the following section, or the end of the assembly.
- A literal pool is a lookup table used to hold literals during assembly and execution.
- The assembler uses literal pools to store some constant data in code sections.
- The literal pool is part of the working memory of a function, but only the constant data in the function.
- The purpose of this function is because some code sections are very long, so the memory addresses to those constants might be out of range of the LDR instruction ([page 482](#)), so the LTORG directive is used to keep those memory addresses in range.

26.76.1 Example

```
AREA    Example, CODE, READONLY
start   BL      func1
func1
; Function body
; Code

; Load into register R1, the memory address of the first literal pool
; LDR R1, [pc, #offset to Literal Pool 1]
LDR     R1,=0x55555555
; Code
MOV     pc,lr      ; End function

; Literal Pool 1 contains literal &55555555.
LTORG

; Clears 4200 bytes of memory starting at current location.
data   SPACE 4200

; Default literal pool is empty.
END
```

26.77 EXPORT or GLOBAL

`EXPORT symbol {[qualifier{}, qualifier}{, qualifier}[]}`

- The `EXPORT` directive declares a symbol that can be used by the linker to resolve symbol references in separate object and library files.
- `GLOBAL` is a synonym for `EXPORT`.
- `symbol` is the symbol name to export, which is case-sensitive.
- `qualifier` can be any of:
 - ▶ `FPREGARGS`, which means that `symbol` refers to a function that expects floating-point arguments to be passed in floating-point registers.
 - ▶ `DATA`, which means that `symbol` refers to a data location rather than a function or a procedure entry point.
 - ▶ `LEAF`, which denotes that the exported function is a leaf function that calls no other functions.
This qualifier is obsolete.

26.77.1 Example

Export the function name `DoAdd` to be used by external modules.

```
AREA   Example, CODE, READONLY
EXPORT DoAdd
DoAdd ADD    R0, R1, R2
```

26.78 IMPORT or EXTERN

`IMPORT symbol {[qualifier{}, qualifier}[]}`

- The `IMPORT` directive provides the assembler with a name that is not defined in the current assembly.
- `EXTERN` is a synonym for `IMPORT`.
- `symbol` is a symbol name defined in a separately assembled source file, object file, or library. The symbol name is case-sensitive.
- `qualifier` can be any of:
 - ▶ `FPREGARGS`, which means that `symbol` defines a function that expects floating-point arguments passed in floating-point registers.
 - ▶ `WEAK`, which prevents the linker from generating an error message if the symbol is not defined elsewhere. It also prevents the linker from searching libraries that are not already included.

26.78.1 Example

Test if a C++ library has been linked, and branches conditionally on the result.

```
AREA   Example, CODE, READONLY
IMPORT __CPP_INITIALISE[WEAK]

LDR R0, __CPP_INITIALISE

CMP R0, #0
BEQ nocplusplus
```

26.79 GET or INCLUDE

GET filename

- The GET directive includes a file within the file being assembled. The included file is assembled.
- INCLUDE is a synonym for GET.
- filename is the name of the file to be included in the assembly. The assembler accepts path names in either UNIX or MS-DOS format.

26.79.1 Example

Includes file_1.s if it exists in the current place, and also include file_2.s from the path given.

```
AREA    Example, CODE, READONLY
GET      file_1.s

GET      C:\Project\file_2.s
```

26.80 Other directives offered by ARM Keil

Directive	Description
